Fig. 14 illustrates a slightly different design of inside micrometer. It has only a few points wherein it differs from the micrometer shown in Fig. 13. Adjustments are made in like manner to the other types of micrometers just described. Adjustment of the zero reading on the micrometer is made through a different method of adjusting the measuring point A. Care should be taken when using this instrument that the effect of temperature does not cause the reading to be in error. Fig. 15 illustrates the tubular type of inside micrometers.

The readings and adjustments are largely made in the same way that have been previously referred to, except in the case of the adjustment of the zero to the correct reading. Point A is adjustable and is made with a lock nut B. Lock nut B should be loosened and point A adjusted until, with the micrometer set at zero, the correct length is obtained. When the correct position of A has been secured (it may be necessary to make more than one trial) the locknut B should be carefully tightened so as not to disturb the setting. A special wrench furnished with the caliper should be used in making adjustments. With the larger sizes, particular attention should be given to the effect of temperature in making adjustments.

Figs. 16A and 16B show another type of inside micrometer caliper and an adoption of this type to the "depth-of-gear-tooth micrometer." The method of reading these two instruments is also essentially the same as previously described, except for the fact that the graduations are inverted, that is to say that the zero is at the opposite end of the hub. Adjustment of the zero on the caliper to the correct reading is somewhat similar to the methods described. Screw C corresponds to screw A (Fig. 11) and screw D is a binding screw as screw B. This adjustment is not required on the depth of gear tooth micrometer as the surface E on which the scriber point rests, is finished flush with the measuring surface F of the jaw of the micrometer, with the micrometer set at zero.

Micrometer Depth Gauge

Fig. 17 shows the adoption of the micrometer to the depth gauge instrument. Readings in thousandths of an inch are obtained in the usual way. To this must be added, of course, the readings in inches, which is obtained directly from the depth the rod extends below the base when the gauge is set at zero. The graduations on this tool are inverted, or in other words similar to those of the inside micrometer shown in Fig. 16.

Adjustment of the zero on the gauge is accomplished by loosening lock nut B and adjusting the hub A. With the gauge set at zero insert the rod so that the gauge reads from 0 in. to ½ in. Then loosen the lock nut B and turn the hub until the end of the rod is flush with the surface C. Then tighten the lock nut B. As is usual with precision instruments, great care must be taken in making adjustments. In all such instruments where various rods are inserted, the chuck fingers must always be delicately handled, so that these parts do not become worn and destroy the accuracy.

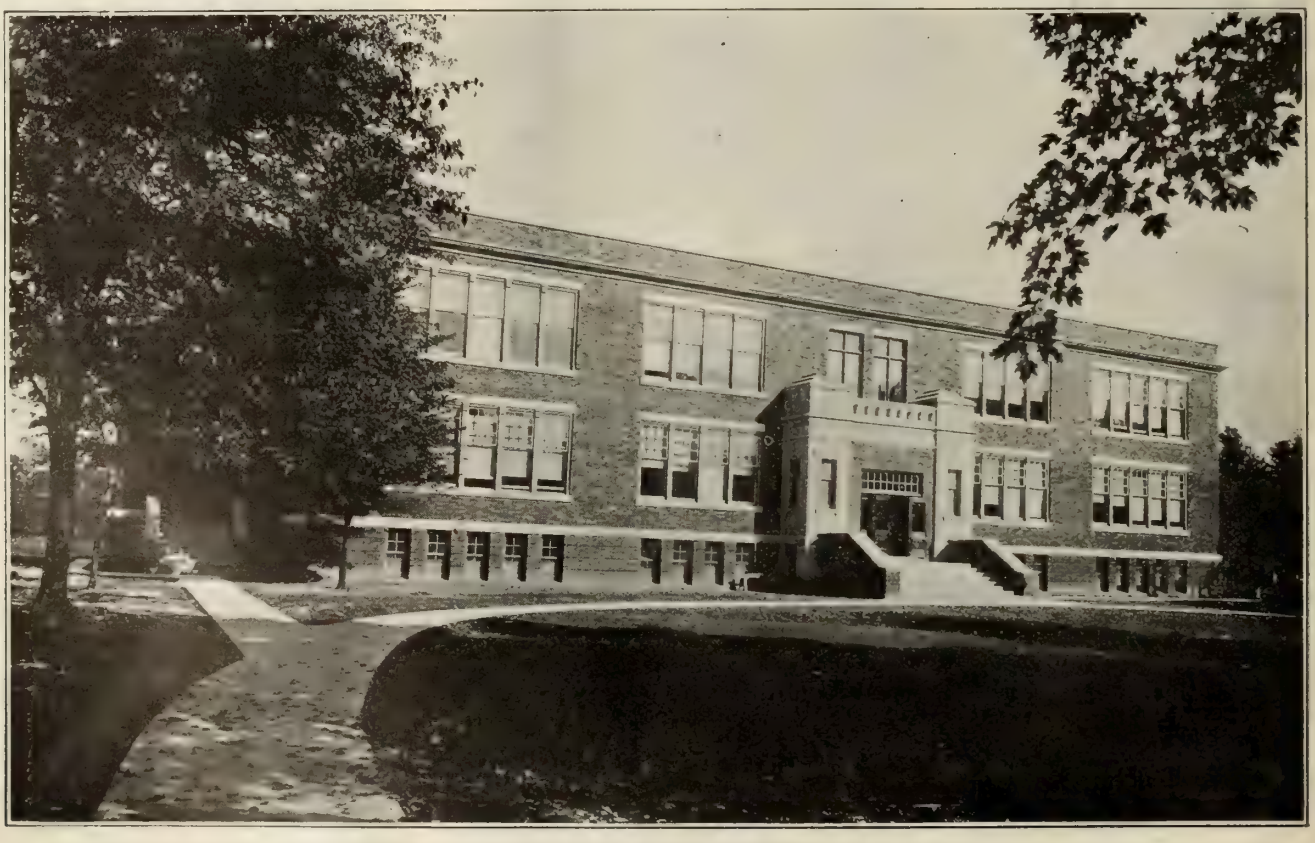
Instruction Based on Industrial Needs

Method of Teaching Changes With Requirements—Local Laboratory Students Assisted — Satisfactory Progress Reported—Dearth of Skilled Workers in Trades

By H. W. McCANAIGH, B.A.
Principal Welland High School

WHEN THE industrial evening classes were started here some years ago, it was thought that each class would be a unit in itself and would offer a chance to make up a deficiency in earlier training, to clear up perplexities met in shop or at home, a difficult bit of measuring and figuring, a job of carpentering or plumbing, and, possibly, for women sewing or cooking. There was little, if any, notion of interdependence of classes; the idea that students would proceed from one class to another was scarcely considered; this feature, to the satisfaction of all, has developed and will exercise some influence in fixing the nature of the classes later. There was no great demand at the start for instruction of any particular sort. Some few mild requests were made for "short story writing," or "picture scenarios," but the majority showed a willingness to avail themselves of any means of self improvement. Classes were thus opened in arithmetic and English, mechanical draughting and shop mathematics, industrial chemistry, applied electricity, wood-working, dressmaking and cooking; to these were added special classes in language, teaching English to French and Italian people.



The class in arithmetic and English picks up students at about third or fourth class public school work; they study on from the simple rules through decimals and fractions such as are used on rules in use by mechanics, ½, ¼, ⅛, etc. In English, the speaking and writing of simple sentences is taught; this, of necessity, includes much spelling, some grammer and composition, and a little reading. This class is always well attended and its students show a tendency to proceed in later years to some of the other classes.

Mechanical Draughting

The class in mechanical draughting includes the mathematics required, students of the present class are much more interested in the calculations than in the work of drawing. The idea is to gain an understanding of working-drawings and blue prints. The course in mathematics includes square and cube root, the solution of triangles by geometry and trigonometry, calculating volumes and weights in different materials, steel, grey iron, brass, etc.; the calculation of pulley sizes, speeds of shafts, and gear ratios. In draughting, freehand sketches are made of machine parts, and for more advanced students there is instruction in machine design and structural engineering. Students have the use of drawing-boards, "T" square, triangles and complete and good sets of instruments; these are the property of the school.

The class in industrial chemistry was inaugurated at request of those employed in the laboratories of the local plants. The work consists of an experimental course in elementary chemistry and qualitative analysis of alloy sand salts. The apparatus and laboratory of the high school is used and, though the class is never large, it has been of great service to several students.

The class in applied electricity, intended to benefit those actually employed in electrical work, is in the main practical, but instruction is given in the theory of operating the different electrical machines, omitting, where possible, advanced mathematics and including elementary electricity and magnetism, electric currents, power transmission and distribution, direct and alternating current generators and motors, transformers, commercial measuring instruments, etc.

General View of Welland High School

The laboratory is equipped with generators, motors and other machines, and instruction is given in the method of connecting in circuit and reading the different instruments; the calibration of instruments and making of calibration curves; methods of measuring resistance and obtaining power factor; commercial tests in generators, motors and transformers; location of trouble in apparatus, and its repair.

The class in woodworking has the use of some fifteen benches equipped with the usual bench tools. Some of the students are workers at the trade, some are "handy-men" who aspire to be mechanics, while others engaged in different work wish to become "handy-men" for jobs about home. They are first taught the use of tools and then the making of the various joints. The progress is surprising. Little more than half a course shows completed a model stair-case, a medicine cabinet, bookshelves, cupboards, jardine stands and stools, some of which would be a credit to a tradesman. Strangely, the boys following the trade do not do so well as do others; they look rather to the speedy completion than to the excellence of the job in hand. It would be an advantage to this class to put in some machines, band-saw, lathe, planer, etc. These are in such general use that a knowledge of them is needful.

For the other classes, cooking, dressmaking and the English classes for foreign people there are well equipped rooms with running water, sinks, tables, cupboards, a range and hot plates electrically heated. The sewing room has tables, sewing machines, electric iron for pressing and all needed fittings.

Classes meet twice in the week and continue for two hours; this seems a long time, but many increase it by coming early and staying late. About forty classes make up the year's work, beginning in November and ending about Easter. The instruction is in all classes to a large extent individual; it must be adapted to each student. The instructor must be capable and versatile. The success of the class centers in the instructor even more than in day-school classes.

Experience in these industrial classes makes it very clear that something must be done to make up for the disappearing apprentice system if the old time craftsman is not to be a thing of the past. Many now working at a trade claim only ability to do certain classes and forms of work. The scarcity of skilled workmen will be greater in a few years; the boys are not being trained. One remedy seems to be in a school, industrial, technical, vocational or whatever called, it should train workmen for the trades indigenous to the locality in which it is situated. Too much consideration should not be given to culture or academic studies. Much culture and good citizenship comes uncalled for to the man with a trade: If attention is given to English, mathematics, and the little physics required to support practical work it will be enough.

MICROMETERS MAKE STANDARDIZATION POSSIBLE

(Continued from page 25)

Screw Thread Micrometer Calipers

Fig. 18 shows the type of micrometer used for measuring pitch diameters of screw threads. The measurements represent the distance between two parallel planes AB and CD. These two planes coincide as at EF when the caliper is set at zero. In making adjustments of zero on the caliper to the correct reading the sleeve G is used for the adjustment. The inner screw H holds the anvil in place. The anvil should be cleaned of dust with a camel hair brush before making adjustments. The caliper reads directly, the pitch diameters of all threads within its range. Tables are prepared giving the proper pitch diameters of all threads within its range. Tables are prepared giving the proper pitch diameters of screw threads, and tap threads which are usually used to confirm readings and sizes.

The pitch diameter of a standard V thread is obtained from the following calculation: The diameter of the screw expressed in inches, minus .866 divided by the number of threads per inch. An example of the calculation is herewith shown. Take a seven-eighths screw, nine threads to the inch. Now .866 divided by the number of threads is .866 divided by 9 and is .0962. Now subtract from ⅞, (which is .875), the figure .0962 just obtained, and the result is .7788 inches which is the pitch diameter of a seven eighths thread. For other types of threads the constant .866 varies. The constant for Whitworth threads is .640. Special anvils and spindles can be obtained for special threads.

The Vernier Caliper

The vernier was invented by Pierre Vernier in 1631 and from him is derived its name. It consists of a small scale on which are a certain number of graduations which equal, in combined length, a certain number of graduations, usually one more or less, on the scale of the tool. It is evident that if, in the same extreme length the vernier has divisions greater or less in number by one, than the scale, there is a small difference between a division on the vernier and a division on the scale. Upon the difference between the vernier and the scale divisions depend the readings, for the vernier is attached to one of the measuring parts, and the scale to the other. This was the principle that was employed in 1851 by the founders of the Brown & Sharpe Co., when they introduced their first vernier caliper measuring to the one thousandth part of an inch. This was their first precision measuring instrument. A modern vernier is shown in Fig. 19.

Reading the Vernier

Fig. 20 shows the vernier used with a scale that is graduated into 40ths or .025 of an inch. The vernier has twenty-five divisions which are numbered every fifth division, and which equal in extreme length, 24 divisions on the scale, or 24 x 1-40 inches and is equal to 24 x .025 inches, or .600 inches. Thus one division on the vernier equals 1-25 of .600 inches which equals .024 inches. Therefore the difference between a division on the scale and a division on the vernier is .025 in.. minus .024 in., which is .001 or the one thousandth part of an inch. When the reading is exact with respect to the number of 40ths of an inch, the zero on the vernier coincides with a graduation on the scale—either inch, tenth, or fortieth, as the case may be. This leaves a space between the scale and the 1, 2, 3, 4, 5, 6, etc. respectively, the difference increasing .001 in. at each vernier division in numerical order until at the 25th graduation, the lines again coincide (see upper part Fig. 20.)

Thus when the first, second or third, etc. line on the vernier coincides with a line on the scale, the zero on the vernier has moved one two or three, etc., thousandths of an inch past the previous fortieth graduation to bring these lines together. Again referring to Fig. 20—to read the caliper, first note the inches, tenths and fortieths of an inch that the zero on the vernier has moved from the zero on the scale and to this reading add the number of thousandths indicated by the line on the vernier that corresponds with a line on the scale. Take the example in the upper part of Fig. 20. The zero graduation on the vernier is shown coinciding with a fortieth graduation on the scale. (The second fortieth beyond an even tenth graduation.) This indicates that the reading is exact with respect to the fortieths of an inch. The reading therefore equals 2,000 plus .300 plus .050 which equals 2.350 inches. The lower part of Fig. 20, however, shows the 18th vernier graduation coinciding with a line on the scale. This indicates that .018 inches should be added to the scale reading. The reading would then equal 2.000 plus .300 plus .050 plus .018 which equals 2.368 inches.

Gear Tooth Verniers

The purpose of the gear tooth vernier caliper, as shown in Fig. 21, is to accurately measure the thickness of gear teeth at the pitch line, or the chordal thickness of the teeth. To measure a tooth, first measure the outside diameter of the gear. If this is larger or smaller than the correct diameter of the gear, allowance must be made when setting the caliper for the distance from the top of the tooth to the pitch line, so that the thickness will be measured at the true pitch diameter. The amount to allow when setting the tongue is one half the difference between the correct diameter which the gear should measure and its actual diameter, noting which is the larger and making the allowance accordingly. Then set the tongue to the amount s in. (Fig. 22) for the given pitch, by means of the scale and vernier, using the tables available to ascertain the distance s in. for the pitch and number of teeth in the gear. Care

Speeding up the Gauging of Threaded Work

Accurate Control of Size—Tap Inspection More Effective—Closer Limits of Tolerance—Gauging Tests Made at Reasonable Cost—Fine Adjustment Possible

MACHINING of plain holes and shafts to definite limits of accuracy is, to-day, a regular operation in most engineering works; it is part of the modern system of manufacture by which high quality interchangeable work can be produced on a commercial basis. In the operation of this system the limit gauge is an essential factor; by its use components are finished on machines to limits which ensure that they will assemble correctly, hand work being practically eliminated. The so-called fitter acts purely as an erector or assembler. There are a number of excellent limit gauges by the use of which the sizes of plain shafts and holes can be efficiently controlled but there is a great need of similar facilities in the production of interchangeable threaded work.

It is not yet generally recognized that the principle hitherto employed of judging the fit of a screw in a threaded hole by its feel or amount of shake is fundamentally wrong. A screw or other threaded part must fill two main requirements. First, it must assemble or, in other words, enter the threaded hole in which it is intended to fit; therefore, none of its elements must be too large. Secondly, it must have a pre-determined mechanical strength; therefore the effective diameter—the true measure of the size of a screw—must not be below a certain limit.

The ring gauge in which we can judge the fit of a screw only by the amount of shake is not a reliable limit gauge since it will pass a screw which is of bad form and low mechanical strength. Such a screw may bear only on the major diameter (which is relatively unimportant) and will be apparently a good fit in the ring gauge although its effective

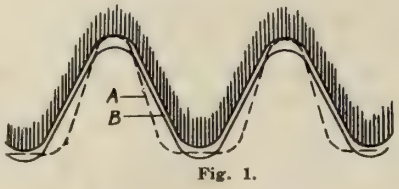


Fig. 1.

diameter is too small. On the other hand a screw which is correct in all elements and commercially perfect may show a certain amount of shake in the ring gauge but will be much stronger than the screw of bad form which shows no shake at all.

Improved Method

To obtain interchangeable threaded work we require a limit gauge system which will ensure not only assemblage but also predetermined mechanical strength in both the screw and the threaded hole in which it fits. The Wickman adjustable thread caliper gauge enables all screws and externally threaded parts to be controlled within any desired limits of accuracy in pitch, effective diameter and incidentally, major and core diameters which are dependent on the effective diameter for their accuracy.

If we can now similarly control the threaded holes we can then produce screws of any predetermined quality and fit which will assemble correctly just as in the case of plain work. It is probable that at least 90 per cent. of all threaded holes are tapped so that a satisfactory limit gauge for controlling taps is an essential factor in the production of interchangeable threaded work. Hitherto there have been no gauging appliances which could be used economically for tap inspection. The projector, the screw diameter measuring machine and the pitch measuring machine are slow and the readings which they give must be finally classified by a skilled man. This will be realized by those who have endeavored to obtain a true indication of the size of a screw from the various readings of effective, major and core diameters, graph of pitch error (making allowance for the effect of pitch error on effective diameter reading) and form of thsead.

The table shown taken from the actual readings of a four-fluted tap, will give some indication of the length of the operation required in determining the accuracy of the tap.

MAJOR DIA.		EFFECTIVE DIA.		CORE DIA.	
1st pair of flutes.	2nd pair of flutes.	1st pair of flutes.	2nd pair of flutes.	1st pair of flutes.	2nd pair of flutes.
008	0075	001	002	006	0055
0085	009	0015	0018	005	0058
009	0085	0023	0027	007	0075
008	010	003	0027	0073	007
0095	009	0027	0029	0075	008
007	0095	0025	0023	008	0078

It will be noted that six readings only were taken on each pair of flutes.

System of Measuring

The major, core and effective diameters were measured on a screw diameter measuring machine; the first was a simple micrometric test; the second necessitated the use of needles and the consequent calculations involving their diameters; the third required special anvils to bed down into the radius at the root of the thread.

Another instrument—a microscopic measuring machine—was brought into use to measure the angle, and the form of thread was obtained by projection. Pitch error was checked on a pitch

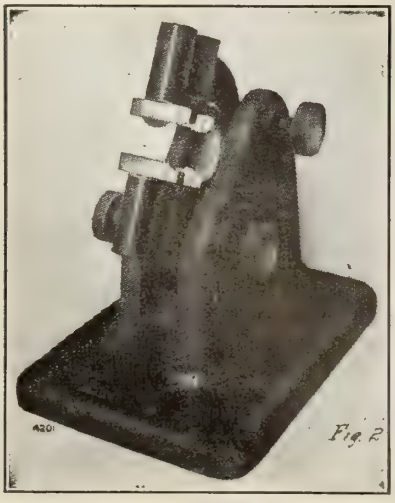

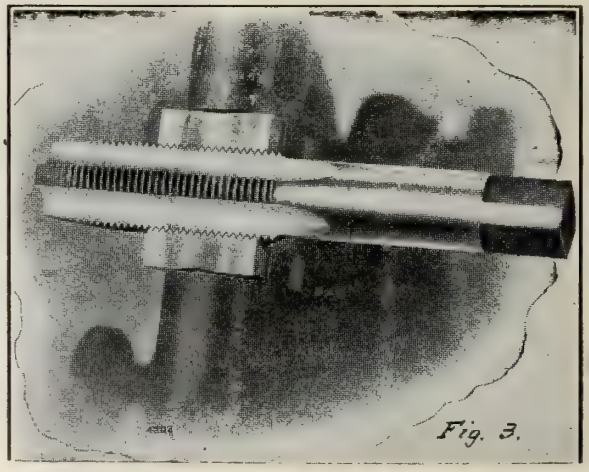

Fig. 2.—Gauging Device.

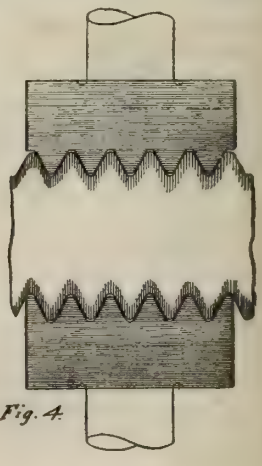

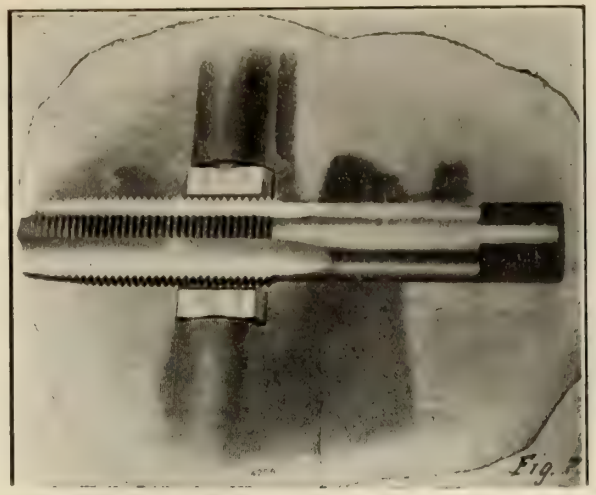

Fig. 3 and 4—Tap passing the full form anvils which are set to maximum effective diameter of tapped hole.

measuring machine and the results from this test plotted on squared paper. After considerable calculations the actual errors in the various elements of the thread on the tap were obtained. The entire test occupied about half an hour of a skilled man's time, the cost, of course, being prohibitive for checking a considerable number of taps. What is required is some form of limit gauge by which every tap used can be quickly inspected and which will reject all those in which any element is either above or below some predetermined limit.

Checking Dimensions

The gauge here described has been developed for this purpose. As shown by Fig. 2, it consists of two limit gauges; the first, which is a "go" and "not go" gauge, controls the pitch and effective diameters; the second, "not go" only, ensures that neither the major nor core diameter of the tap is too small. The operation of the gauge is as follows:—the outside or "go" anvils of the first gauge, which are full form, are set to the maximum effective diameter. No element of a tap which passes through these anvils as shown in Figs. 3 and 4 can be too large. The inside or "not go" anvils check the effective diameter only but the combined tests in this first gauge also check the pitch.

The effective diameter of a screw is increased by approximately twice the amount of pitch error, if, therefore, the pitch error of a tap exceeded the limit allowed, the effective diameter would have to be correspondingly reduced before a tap would pass the outside or "go" anvils; if, however, the effective diameter were reduced below the limit allowed, the tap would pass through the inside or "not go" anvils and would be consequently rejected. The action of these "not go" anvils is shown in Figs. 5 and 6. It will be noticed that the threads of the anvils are cleared away at the crest and root so that they check only the effective diameter of the tap. In the second gauge the outside anvils which are "not go" are set to the minimum major diameter of the tapped hole and ensure that the major diameter of the tap shall not be below the limit.

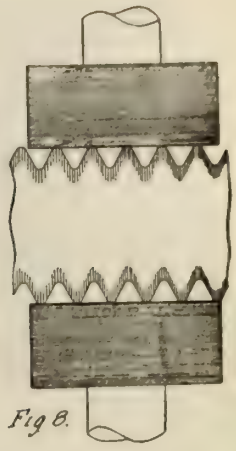

Fig. 7 and 8—Tap in "not go" dia. anvils, set to minimum major diameter of tapped hole.

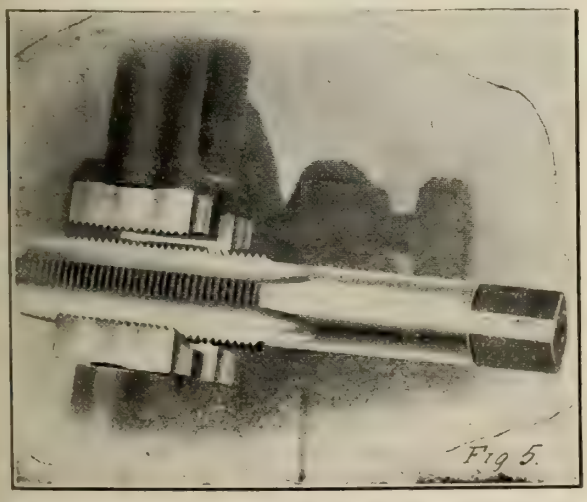
Figs. 7 and 8 show this. The inside anvils, also "not go," are set to the minimum core diameter of the tapped hole. The threads shown in Figs. 9 and 10 are of a profile which bears only on the core diameter of the tap and therefore ensure that this element is not below the limit. It will be obvious that every tap which passes this inspection has undergone a searching test and that no element has escaped observation; further that the test is made very rapidly (actually in from 30 to 40 seconds) and can be efficiently carried out by anyone with ordinary intelligence. By the use of this gauge both makers and users can test their taps at a reasonable cost and no inaccurate tap need find its way into the shop. The anvils can be easily adjusted so that any desired limits may be worked to: when set, both the adjusting and locking screws are covered with a lead seal so that the gauge is tamper proof. Wear on the anvils is practically negligible but should this take place after long use, the faces can be ground back slightly and when re-adjusted the gauge is again ready for use.

Adjusting and Setting

Fig. 11 shows the details of construction. The adjusting screw is covered by a locking screw which in its turn is covered by a lead seal closed into the recess at the top of the gauge by means of a special press. This press indents the firm's monogram or trade mark in the seal, thus preventing any unauthorized tampering or alteration. The inspector, on issuing a gauge to the shop, can feel confident that he will not have spoilt work returned to him together with tampered gauges. The press, when out of use, can be locked with a padlock and the key retained by the inspector.

The adjustment of the gauge is very simple and is such as permits of extreme accuracy. The stem of the anvil, which is hardened and lapped to fit the hole, is coned out on the top end to an angle of 60 deg.; in this rests a hardened steel ball. The adjusting screw, which is also hardened, has a similar cone underneath it and presses down on the same steel ball. The locking screw, the head of which bears in a counterbore on the top of the gauge, passes through the hardened adjusting screw, through the clearance hole in the steel ball and into a tapped hole at the bottom of the countersink of the stem of the anvil. Two holes are provided in the head of the locking screw and a special peg spanner (with prongs which go through these holes and enter the slots of the adjusting screw) is used for setting the gauge.

In setting the gauge, the locking screw is first released a few turns and by inserting the peg spanner through the holes in the locking screw the pegs engage the slots in the adjusting screw. By this means the cone of the adjusting screw will push down the hardened steel ball which in its turn will push down the stem of the anvil. The gauge is adjusted until it grips the reference piece slightly tighter than is required. By giving the locking screw an extra twist with a screw driver it is possible to get any desired pressure between the anvil and the setting gauge as the hardened steel ball is elastically compressible to a few thousandths of an inch. For example, it is possible with this adjustment to pick up a set of slip gauges between the anvils; give the locking screw an extra slight turn, and the gauge will not pick up the slips. Release slightly and the anvils will grip the gauges once more. This system of adjustment is the finest possible and when once locked it is im-



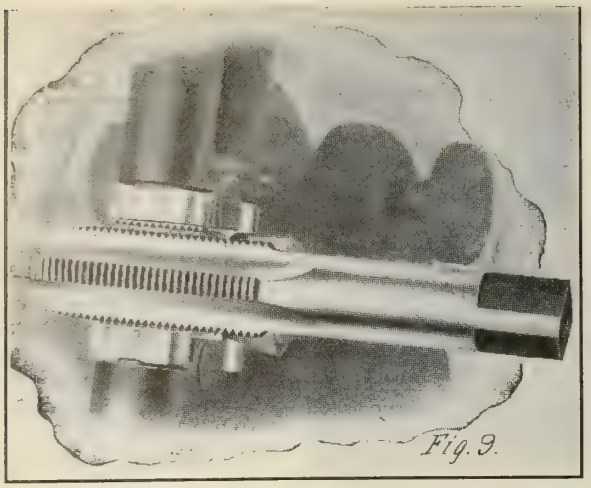


Fig. 5 and 6.—Tap in "not go" effective diameter anvils, set to maximum effective diameter of tapped hole.

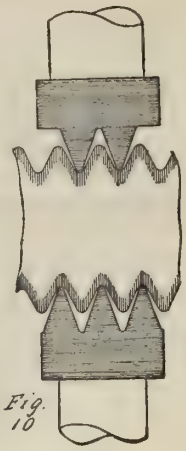

Fig. 9 and 10—Tap in "not go" core diameter anvils, set to minimum core diameter of tapped hole.

possible for any backlash to be existent. When the gauge is finally sealed, tampering becomes an impossibility and an attempt to set the gauge in a vise would result in the fracture of the frame.

Desired Limits

The limits of accuracy to which taps should be controlled are matters for determination. they will be greater than those allowed on plain work as it is not possible to produce tapped holes with the same degree of accuracy as reamed or ground holes. Once a satisfactory limit has been found, no trouble need be experienced from tapped

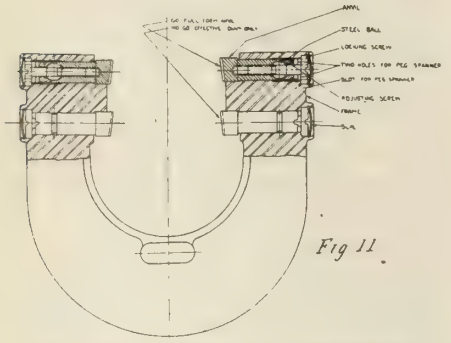

Fig. 11.—Line drawing of gauge showing internal mechanism.

holes which are outside this limit as now frequently occurs. Nothing will be gained by attempting to work to limits finer than those which will give interchangeable threaded work. The manufacture of accurate taps is not a simple undertaking but it will be greatly assisted by this simple and efficient method of inspection.

SYSTEM AS AN OBSTRUCTIONIST

By Donald A. Hampson

At a recent meeting of the Am. Soc. of Mech. Eng., one of the points brought out in a discussion of material handling systems and machinery was that each salesman, each engineer, was so anxious to get his own particular product installed in customers' plants that he overlooked entirely the adaptability of that product to the local needs and the fact that plant conditions often cried loudly for a system quite opposite to the one it was proposed to install. And there is the curse of the whole system business—be it time clocks, conveying machinery, stock indexes, job tickets, or office filing systems. Before putting in any one of these aids to business, executives should study well present conditions and costs in their plants, comparing them with the same after the installation, and strive to avoid losses such as were incurred by the plants cited in the following.

The Ideal Co., had a small fine plant but the field for their product was limited and it was decided to take in job work too. It was also decided to do things systematically, to index and cross index and to send a routing card through the machine shop with each job. It sounded fine, and they received their full share of job work for a while, people being attracted by the company's reputation in the machinery field. But after a while it began to dawn on these same customers that they lost time and that they paid more. Why? If a job was brought in, it went first to the shop office. There is was looked over by a well fed engineer who smoked good cigars (himself) and passed an opinion on the job, together with a brief resume of the causes and effect of such a break. Meanwhile a girl had been called and began to fill out the various cards. The shop foreman, having been called, arrived in due time, looked over the job, exchanged opinions with the office man, and the work passed into the shop. A splendid system!

The customer felt that his work was in the hands of men who knew, and so it was. However, it dawned on him later that a half hour was lost in the office and that he paid for that half hour at a good rate. Then, if he had a hurry job he lost that much time in starting. And if the job was a simple one, as removing a broken-off bolt, it took as long to get the system working first as it did to do the work later. Now, at the other shops in the locality, you saw the foreman or superintendent right off. No cigars and no girls and no system. The shops themselves were just as big and as well equipped—the executive looked over the work, told what he would have to do and when the work would be finished—the entire process did not take five minutes and if it was a hurry up job (that could possibly be started right away), it was in the hands of a workman at the end of that five minutes. Which is the better way?

The ..... Brake Shoe & Foundry Co. had an elaborate system in their plant. A clerk could tell you in a minute how many brake shoe heads from Patt. BM-548 there were in stock, where this or that special job was and when it would be finished, how many tons of pig iron were in the bins. Quite recently an order was received for a certain brake shoe, a pattern that the records showed they were entirely out of, and yet—three car loads were shipped out in the next ten hours, and all from stock! Somebody had neglected to make the necessary entries.

A manufacturing plant near us installed a "system" in 1914. That system is not in use to-day, though the business has grown in that time. There were a hundred men employed in 1914 and the plant covered several acres of ground. It was thought that a modern system for a business of that size would be a money saver and far better than the old method wherein one clerk did the work, spending part of the time in the office and the rest in gathering foremen's figures daily at the various desks. But it was found that the new system required the full time of three clerks and that the foremen, who were not allowed to do any more clerical work, were continually being pestered by the clerks as to technical details.

CARBURIZING HEAVY SECTIONS

Commenting on the carburizing of heavy sections, W. E. McInerney says that modern practice requires a carburization for a depth of one inch or more. "Getting the proper graduation from the surface to the required depth, and not causing excessive concentration in the surface strata is the problem that confronts the heat treater, and the carburizing compound manufacturer," comments the above writer.

He mentions that of the three carburizing agents, viz., liquid, solid, or gaseous, the solids have been more extensively used, and that there are certain requirements that must be met by the agent before it will prove satisfactory for use in heavy section carburizing, a few of which are:—

1. Uniformity as to composition and physical qualities, grain or pellet size. 2. Freedom from sulphur in injurious amounts less than 0.5 per cent. 3. Freedom from internal combustion. 4. It should not flux or fuse at any temperature up to 2,100 degrees Fahr. 5. It should not coke or cake on the plate making it difficult to remove and 6. It should also have a good bearing value and minimum shrinkage so as not to crush excessively in use.

Home made carburizers, says Mr. McInerney, have not proven any more economical than the commercial ones, and are not as satisfactory due to the difficulty in properly mixing them.

Heat Treatment Not Always Cause of Failure

Sharp Corners Should be Avoided—Fillets Are Very Necessary —Change In Design Will Often Solve Hardener's Difficulty— Various Causes for Tool Failure—Co-operation Is Necessary

By CHAS. A. BROOKS

IN ONE particular pneumatic rivet die which came to the attention of the author recently, four defects were discovered. The end which the piston plunger struck, was not sufficiently crowned, the fillet at the shoulder was entirely too small, machine tool lines were in evidence at this point, and there were sharp shoulders where the spring retainers gripped. These defects were a result of faulty design or ignorance, yet when the set proved inefficient, the difficulty was assigned to an improper temper by the man who used it. But the steel treater was not at fault. In another case of intricately shaped car molding dies, failure was also given as an improper temper. Here the true trouble was a slight difference in the oversize thickness of metal rolled, insufficient space between the male and female die, as well as the failure to reheat the metal after the oxyacetylene weld before continuing the operation. Second heatings at a slow gradual cooling down would have relieved the hard state of the metal. In fact, the metal was as hard after the weld as was the small raised sharp edged ring-shaped part of the third step finishing dies. Most steel treaters appreciate the hard condition of 1-16 to ⅛-inch steel plate after oxyacetylene welding. Until careful attention was given to a second heating with slow cooling down, difficulty was experienced. This with a closer inspection of gauge size of stock to be rolled overcame all trouble with roll die failures.

The Value of The Fillet

Punches operating on ship plate up to 1-inch thick gave good service but when extra heavy plate 1⅛ to 1½ inch thick was placed under the punch, trouble arose. This was assigned to faulty heat treating, but examination showed that the greater part of the breakage occurred at a point close to the sharp shoulder where the machine chuck gripped the punch. The punches were annealed and returned to the machine shop to be turned back ⅛ inch, leaving a fillet where the sharp shoulder was before. After this change and the identical heat treatment as before, the punches stood up well on the heavier plate. This proved that the original heat treatment was not in error. In a similar instance of a tool for bellying out large boiler tubes before beading them, design was at fault. This tool, which was of the pneumatic type, was of a cut off cone shape with the bellying end considerably out of proportion to the plunger part that fits into the riveting machine. Each die had a short life and several kegs of broken ones had accumulated. A new shape of tool was suggested and although apparently of an impractical nature six of them were forged. After months of service, the same six are still being used. A record was kept up to 20,000 tubes processed on one die, this being a sufficient number to prove that the new type was practical and efficient.

A paper presented before the Philadelphia Chapter. The author is foreman steel treater, Bethelhem Shipbuilding Corp., Ltd., Wilmington, Del.

Change of Design

Changes in design of an offset die used for bucking up rivets also proved beneficial to a previously unsatisfactory tool. The changes consisted of generous fillets and providing a longer taper between the heavy and light body parts of the tool, as well as holding the body end of the tool to as small a diameter as possible to overcome difference in weight resistance. These modifications overcame practically all trouble and discredited the theory of improper heat treatment. Making the reacting hammer pistons from 16.5 per cent. tungsten steel instead of high carbon steel overcame wear and breakage on this type of tool. A more recent change of using a slightly shorter piston of the same weight of the longer carbon steel piston has resulted in a faster stroke and rivets driven quicker. Sticking in the chamber of the machine, such as often occurs with carbon tool steel however tempered or crowned, has been eliminated entirely.

A general rule of the average steel treater seems to be the giving of extreme hardness consistent with no breakage. It is also a common belief that the frequent grinding necessitated in high speed steel is an indication that the tools are too soft. This is not always true. With a high speed tungsten steel, the hardest point possible for production may be obtained together with the necessary hardness, but the cutting edge may not have a satisfactory edge retaining property, thereby requiring frequent grinding. A good tool must not have this latter property. A high speed steel containing 16 or 17 per cent. tungsten in its hardest state shows edge crumbling but a lower hardening heat with oil quenching ending at flash and a slow cooling will produce a tool, which although considerably softer, will require less grinding and give longer service. The author recalls one steel salesman, who in demonstrating a good high speed steel, lost the sale because he did not understand the practicability of obtaining a lasting cutting edge along with the highest degree of hardness.

Of course, there are various causes for tool failure such as grinding too great a clearance, pressing too hard on a dry wheel and then dipping into water, and taking too heavy a cut in the machine. More care must be used as to the service required from the tool; pneumatic vibration, rigid holding for machine service or punch or shear service. The tools must be designed suited for each service. This is just as essential as the steel used and treatment given. The heat treater, toolroom foreman and superintendent must co-operate closely to this end. Many failures will be offset by making a study of the tool or machine part prior to making the design. Tools may be forged or machined easily but they will not always do the work expected. In following old standards, we are too prone to neglect possible causes of failure other than heat treatment.

Too many failures are laid at the door of the steel treater. Thus it is essential that he state explicitly his views when he knows failures are not the result of heat treatment. For the advancement of science his views must be considered. It is impossible to make tools or machines stand up in service unless they are given proper care.

THREAD CUTTING POINTERS

In a recent issue of "Threads" appear the following questions and answers on thread problems.

Can you tell me what causes chasers to pick up or load up with brass between the threads, also what is the best lubricant to use for brass, if any?

As a rule we find that chaser teeth becoming clogged with chips is due to chasers being dull so that they do not free the chips properly. We would suggest that you look into this, and should you be unable to overcome your trouble, suggest that you return a set of the chasers to us for examination. We strongly recommend the use of a lubricant for all threading. However, most manufacturers thread brass without any lubricant. For brass work it is not necessary to use a heavy oil, but simply a liquid that will cool the cutters, preventing the drawing of the temper.

Why is it that certain chasers will not thread straight? Die Head is practically new? It is possible that the chasers may not be inserted into the die head properly. The machine may be out of alignment. The turret may be forced faster than the chasers can cut, or it may be held back. All of the chasers of the set may not be cutting properly. That is, one or more of the chasers may be cutting ahead or behind. It might be well to test the chasers on a trial piece of stock by stopping them on the cut to see if all chasers of the set are cutting properly. All the cutting should be done on the chamfer, and not back on the chasers.

Recent Developments in Mechanical World

Power Transmission By Chain

THERE is no doubt that the use of the toothed chain is not taken full advantage of by works engineers and others. Very often its installation will solve transmission difficulties, and although it is an expensive article to produce, in many cases it would be a cheap investment. There is, writes a correspondent in the Manchester Guardian Commercial, one essential to successful operation, and that is an oil-bath gear case. These cases are built of sheet steel, and are cheap. Usually they have a simple pump which delivers a stream of oil on to the working side of the chain, the consumption of oil being quite small. They may under certain circumstances have to run exposed; if so, a periodical soaking is essential. In motor car work they would run in the general oiling system. Outside the foregoing adaptations there would appear to be a good field for the chain in intricate machines as a substitute for gearing, and the suggestion is commended to designers and inventors. It should be noted that a toothed chain can be made to transmit power to several wheels confined in a very small space.

Increasing Output of Drilling Machines

IF A CORRECT record of the actual running times of drilling machines were obtained it would be found in many cases to be but a small proportion of the working day. This, of course, is due to the antiquated methods so often employed when fixing and changing the work, and the disparity is very marked on the modern machine where the employment of high-speed steel makes the actual cutting time of very short duration. This question of the provision of suitable means for quickly handling and changing the work to be drilled, says a writer in Engineering and Industrial Management, has in certain quarters received more attention of late, judging by the number of angle plates, machine vices and work tables now in use and arranged to swivel in one or more directions. Their application is, of course, suitable not only to the drilling machine, but to the majority of machine tools. In the modern drilling machine, where the drill is forced to its utmost limit, if increased output and the consequent reduction of production costs is desired, it is imperative to effect economies in fixing the work and so keep the machine fully employed and running the maximum percentage of cutting time.

* * * *

Pyrometers and Heat Treatment

THAT THE best results will never be obtained with a pyrometer unless the operator knows something about its construction, principle, and intricacy, is pointed out in the Edgar Allen News, the house organ of the Imperial Steel Works. Heat-treatment plant workers should know how to tell temperatures by color tints. The pyrometer, it must be remembered, indicates the temperature of a limited portion of the furnace interior only, and a correct estimate of the heating chamber's temperature cannot be formed unless the eye is used to compare the color of that portion with that of the rest. Surprising ignorance is often shown in regard to pyrometers. In one case, an operator had noticed that the thermo-couple of this instrument was broken, but instead of welding the elements, he had merely twisted them together and carried on. He had had the pyrometer for some years without once having it tested or regulated. In another instance the thermo-couple was inserted without protection into the heating chamber through a top-vent near the centre, and the furnace heat was kept at 1800 deg. Cent. for some hours. Reckless heating of this kind simply invites inaccurate results.

Lubrication of Air Compressors

ONE OF THE most important items in running an air compressor is lubrication. In modern machines the running parts are usually inclosed in a crank case and run in oil. The oil is made to circulate from the bottom of the bed over all the bearings, pins and guides and then runs back into the bottom of the bed again. The air cylinders are sometimes lubricated by a sight-feed oiler, so designed that the pulsation of the air pressure assists the feed of the oil. Also, sometimes the air cylinders are lubricated with a positively driven oil pump. Two principles should be maintained in lubricating an air cylinder, says a writer in the Engineering World. The first is to use only the right kind of oil, and the second is to use it sparingly. To be the right kind, air oil should be rather light-bodied and have a flash-point above 260 deg. Fah. for compound compression to 100 lb. pressure and 360 deg. to 375 deg. Fah. for single-stage to the same pressure.

* * * *

Melting Metal With Fuel Oil

ALTHOUGH crucible furnaces have received considerable attention in regard to heating with both gas and oil, there has not been much effort made in respect to the use of oil in furnaces where the metal is melted in contact with the fuel as in cupola melting. The ordinary reverberatory air furnace can be adopted for either oil or gas heating. To melt metals heat only is needed, no matter from what source derived, as melting is a matter quite apart from the reduction of metals from their ores, in which solid fuel is probably necessary for other than its heat producing properties. In the production of the necessary heat from oil combustion, continues The Practical Engineer, it would seem very much as if the oil should be injected into the furnace with the necessary amount of air, to ensure complete combustion the oil necessarily being in a very finely divided state and that probably the combustion chamber should be preheated at first to assist the automizing of the oil.

* * * *

Cobalt Magnet Steel

A NEW formula for making magnet steel is coming into use, the principal change from the ordinary practice being the employment in its composition of cobalt instead of tungsten. Hitherto, such steel has contained about 5½ per cent of tungsten, and the substitution of about 15 per cent of cobalt raises the coercive force of the material from 60 to 250, making it possible to use smaller magnets. The London Ironmonger states that the use of the new steel necessitates a new form of magnet, consisting merely of two small flat plates of steel placed on the sides of the armature, hence if it should come into general use the familiar horseshoe-shaped magnet will disappear. As yet, however, cobalt magnet steel is only in the experimental stage. Cobalt magnet steel costs three or four times as much as tungsten steel, but a much smaller magnet is required to do a given amount of work.

* * * *

INVESTIGATIONS at the Pittsburgh Experiment Station on the technology of aluminum include studies of causes for and prevention of cracks in aluminum-alloy castings; disintegration of aluminum-manganese alloys; analysis of aluminum and aluminum alloys; the contraction and shrinkage of aluminum alloys; and the effect of remelting aluminum alloys.

Practical Ideas for Shop Executives

MANUFACTURE OF VALVE RODS

By G. Blake

Sketch No. 1 illustrates the type of valve rod under consideration. It was during the latter part of the war, early in 1918, that the writer was called upon to increase production of the above rod. Previously the rod was machined as follows: (1) Rough, and finish diameter (full length of rod) to diameter of screwed portion, form ball on end, screw, and part off on capstan. (2) Centre screwed end, undercut and finish diameter from A to B on centre

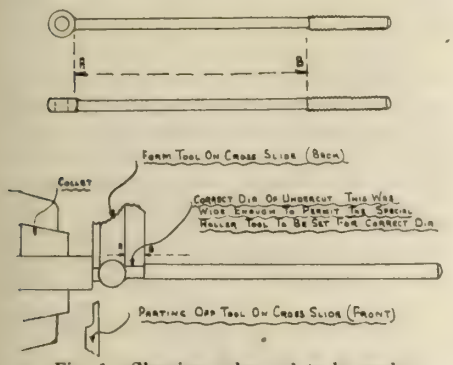

Fig. 1.—Showing valve rod to be made.

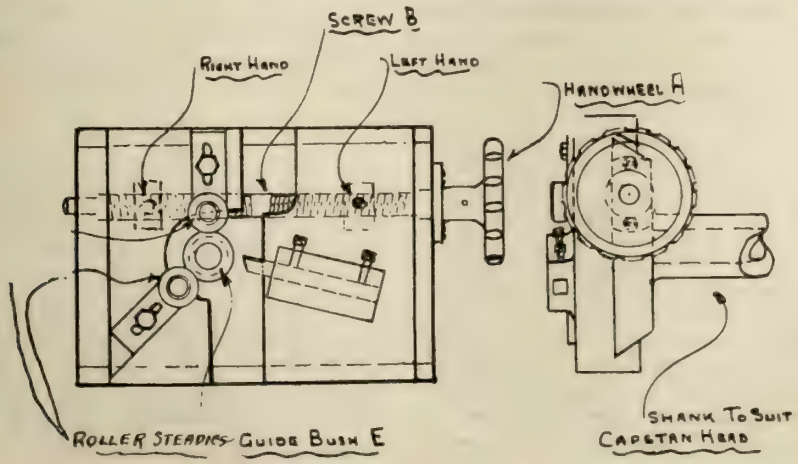
lathe. (3) Mill flats on head in gangs, using straddle cutters on milling machine. (4) Drill and ream eye in head in jig, using floating reamer on drilling machine. (5) Trim up heads on bench.

It took two men working full time to keep up with operation 1, as the undercutting was important and the finished diameter was less than 9-32 in. and the length 8 in. Only light cuts could be taken, even when using the travelling steady, in addition to tying up two men and two centre lathes. The operation was very costly in comparison to the other operations which were performed by boys and the writer decided that the centre lathe operation could be dispensed with and the undercutting done on the capstan in operation.

A special adjustable roller steady tool box was designed. Sketch No. 2 shows the idea, the aim of the toolholder being that by turning the small handwheel A, the rollers and tool could be advanced or withdrawn simultaneously by means of the screw B which was threaded right and left handed, the roller holders in addition could be adjusted independently from their own slide. The sequence of operations on the new method is as follows:

(1) Round the screw end, open collet and set rod to length, rough and finish turn diameter (full length) and while finish turning diameter, form ball end, using cross slide; the form tool (circular) was made as per sketch, the part at A B was for turning the rod to its proper diameter, when undercut. The reason for this was that the special tool box could be adjusted by means of the handwheel A to the correct diameter. The sketch of the rod after the forming process illustrates what is meant, then when the toolbox was set, the capstan traverse was reversed so that the tool moved away from the headstock of the machine, the cutting edge of the tool being inside the box, instead of outside, as is the case in ordinary tool box turning; a hardened guide bush E in the toolbox guided the rod and kept it steady during the undercutting process. The shank of the toolbox was hollow. The end was then screwed with a collapsing die head and this with the parting off completed the first operation. The other operations were as before, cutting out of course the undercutting on the centre lathes, the ultimate result being that production was considerably increased, and the releasing of two centre lathes and their operators for other work and in addition to the increase in production the manufacturing cost per rod was decreased by over 25 per cent. However, before the firm could benefit by the new method, the contract was cancelled and other work taken in hand, yet the methods described go to show the adaptability of the capstan when tooled up properly.



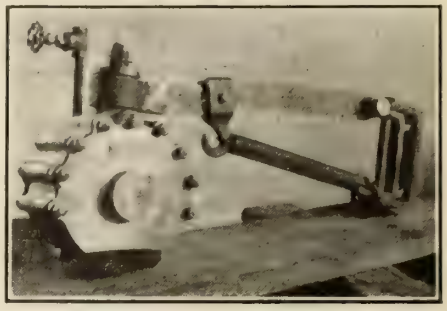


Fig. 2.—Adjustable roller steady tool box.

FLANGE AND CABLE OILER

By G. L. Ingram

An interesting device for continuous lubrication of car wheel flanges, cables, etc., is shown in the accompanying illustration. It consists of a cast steel wheel hollowed out on each side with a fitted flange groove, the portion bearing on the flange or cable being perforated with small holes. The wheel rotates on a ball race, cones are supported on a stationary axle through which the oil feeds to the centre of the wheel.

Flange and cable oiler.

The wheel is propelled by rolling contact and the centrifugal force thus created passes the oil through the holes on the surface requiring lubricant. It is automatic in its action, insofar as it feeds only when the object is moving and ceases when flange or cable stops.

The wheel is enclosed in a housing suspended to a bracket with spring connection. The purpose of the spring is to take care of the various movements that the oiler may be subjected to. The hinged bracket prevents lateral play and keeps the oiler in position. The device is satisfactory in operation and lessens, considerably, the friction and wear on rails and driving wheel tyres, and insures longer life to cables. The wheel is enclosed on each side with plates to hold oil as it is fed in through the axle.

DO BELTS SLIP AS SUPPOSED?

By W. F. Schaphorst

A machinist wrote an interesting article some time ago under the above title. His analysis was correct as far as his formulas were concerned, but he didn't fully answer his own question which he used as a heading. The correct answer is:—Yes, belts slip when they are overloaded.

One would infer from this machinist's answer, or analysis, that belts don't slip at all and that the difference in pulley speeds, if there is a difference at all, is due entirely to belt thickness. In an article of mine published some time

ago, I gave this formula for computing the percentage of belt slip:—Per cent. of belt slip equals:—

$$100 - \frac{100\ r\ (d + t)}{R\quad (D + t)}$$

r = r. p. m. of the driven pulley;
R = r. p. m. of the driving pulley;
d = diameter, inches, of driven pulley;
D = diameter, inches, of driving pulley;
t = thickness of belt in inches.

If a belt is not pulling any load the pulley speeds may be accurately computed by the use of ordinary formulas, but just as soon as the belt is loaded one side of the belt becomes tighter than the other, it stretches, and we have a longer belt going onto the driving pulley than comes off. The compensation for this difference in length results in "belt creep." A good formula for computing belt creep will be found in Goodman's excellent treatise, "Mechanics Applied to Engineering." In that formula the co-efficient of elasticity of the belting material is included.

TURNING RADII WITH SPECIAL ATTACHMENTS

By J. Homewood

I have herewith shown on three different drawings, methods to produce radii when the quantity to be machined is sufficient to cover the cost of attachments. There are three different kinds of jobs under consideration in this article, one is a shallow spherical surface to be turned out, one is a shallow spherical end to be put on a corresponding piece, in this case a punch and die to produce a spherical pan. The third is a method used to turn out dies to produce deep round work. In the first case, Fig. 1 shows a method that can be used. This consists of a link C that is pivoted on a piece B which is fastened to the ways of the lathe between the carriage and the head of the lathe. A small bracket is secured to the cross slide of the lathe. The compound rest is turned around, as shown, to facilitate feeding the tool to the work. A cam of the radius to be turned on the piece can be substituted for the link if desired. When different radii are to be turned, either individual links can be made up or else one can be made with a turnbuckle to be adjusted to the different lengths of the radii.

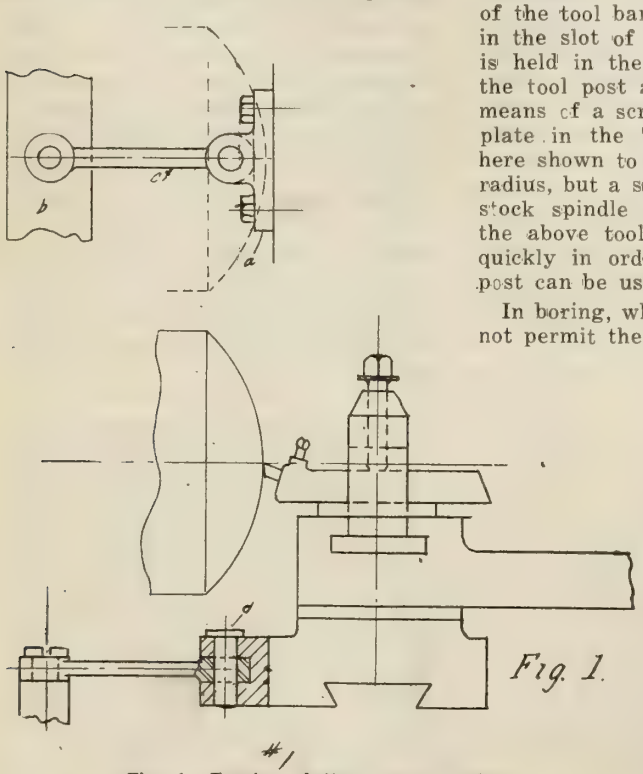

Fig. 1.—Turning shallow convex surface.

Here we have a case where a concave spherical finish is desired. The tool bar A pivots from the support held in the tailstock with a taper shank. This tool bar can be made to provide for slight adjustment if desired. On the bottom of the tool bar is a pin C which slides in the slot of the plate D. This plate is held in the slot usually allotted to the tool post and is fastened down by means of a screw going through to the plate in the T-slot. No provision is here shown to adjust the length of the radius, but a slight advance of the tailstock spindle will provide feed. Like the above tool, a pin can be removed quickly in order that the regular tool post can be used.

In boring, where the conditions would not permit the use of the device shown in Fig. 2 owing to interferences, the method illustrated is the one where the nut is disconnected from the cross-slide and a link A attached thereon which is fastened to a rigid bracket with provisions for adjustment. This link can be substituted by a cam located at the back of the lathe where a roller is guided through the proper raidus.

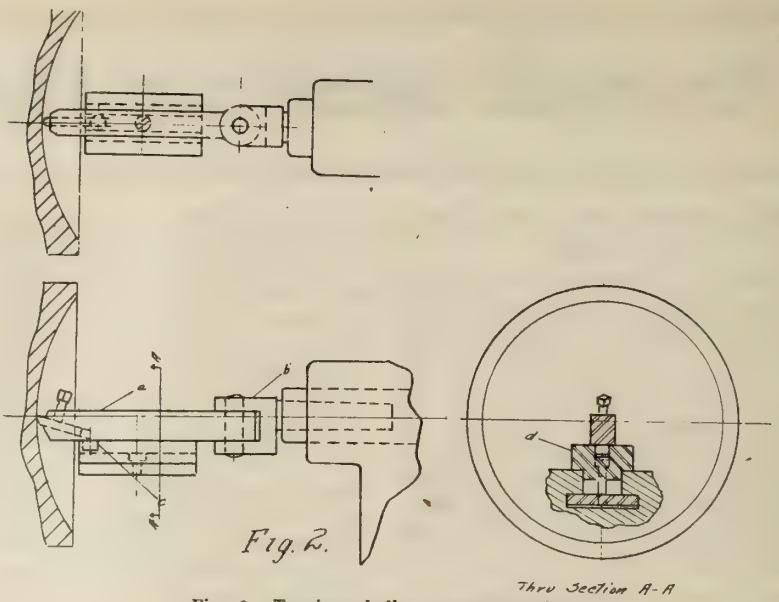

Fig. 2.—Turning shallow concave surface.

GAUGING 15-TOOTH CUTTER

By D. J.

A reamer with 15 teeth is to be ground to ream a hole 2 in. in diameter. What will the reamer measure across the diagonal, or is there a better way to gauge it?

Weights of steel rounds, squares and hexagons, in lb. per ft., are given in a blue-printed wall chart issued by the Betz-Pierce Co., Cleveland. Rounds are covered from ⅛ in. to 6½ in.; squares, from 3-16 in. to 4 in.; hexagons, from 3-16 in. to 2¼ in. In all cases the metric size is given alongside its inch equivalent. Copies of this chart will be furnished by the company on request.

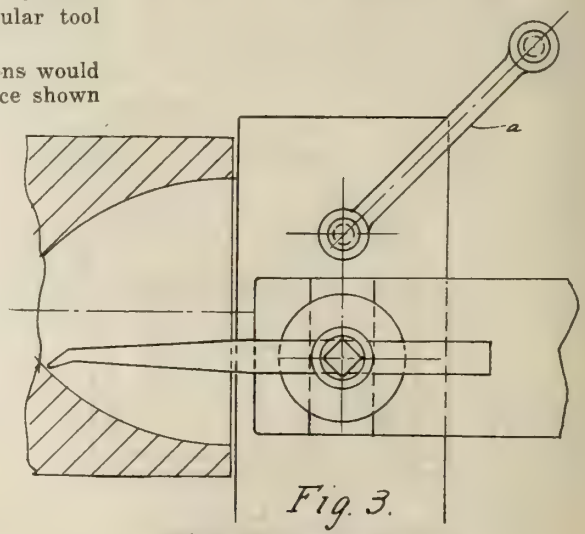

Fig. 3.—Deep concave turning.

New Things in Shop Equipment

PLUG AND TEMPLET THREAD GAUGES

Another line of adjustable templet thread gauges has been recently marketed. The templet gauges are made in two styles, either with one half-way slot on the inside of the gauge or two half-way slots on the outside which lead to the periphery. The latter style furnishes a fuller contact for the threads of the work, a feature which is especially interesting to small gauge users. The plug gauge is fitted at one end with a thread plug, and at the opposite end with a plain plug equal in diameter to that of the root of the thread that it is intended to gauge. Both the threaded and the solid plug are readily replacable as they become worn. The gauges are made regularly for all sizes of standard threads, United States standard, Whitworth, S. A. E., etc., from 3/16 inch diameter upwards. Special threads can be obtained if desired. The manufacturers of the gauges are the Superior Thread Gauge Mfg. Co., Inc., of Brooklyn, N. Y.

FOUR WAY DRILLING MACHINE

The original idea of a four way drilling machine appeared some time ago, but recently a new application of the old principal has made its appearance in the form of a machine for drilling four bearing holes in the upper and lower sections of tractor rear axle housings. A special work holding fixture is necessitated, which is in reality a part of the machine. One-half of the housing is placed in the fixture and located by means of guide pins which engage two holes that have been drilled previously. The other half of the housing is then placed in the fixture and the two parts are held together firmly while the drilling operation takes place. When the housing is removed, the gripping jaws of the fixture are released and the upper half lifted out. The lower half is ejected by means of a lever operated mechanism. The machine and fixture are manufactured by the Reed-Prentice Co., Worcester, Mass.

NEW AIR GUN

A brass compressed air gun for use in machine shops for blowing chips and dirt from the tables of machines, and for cleaning taps, dies, and other tools has recently been placed on the market. The design is such that the loss of air by leakage is practically eliminated, as the gun has a disc that can be readily renewed as it becomes worn. The disc acts as a valve and is accessible through the removing of a small plug which screws into the bottom of the frame. The gun is operated through the depressing of a knob by thumb pressure. When the air is shut off a spring keeps the disc pressed firmly against its seat. The stem of the bottom does not need to be packed as it is in the discharge side of the gun. The gun may be used with any sized hose by simply selecting a proper nipple. The gun is manufactured by Jenkins Bros., New York City.

TILTING ARBOR WOOD SAW

A wood cutting saw on which the arbor can be tilted to any angle up to 45 degrees, and which is therefore particularly adapted for pattern shop work has recently been placed on the market. The table of the machine is always in a horizontal plane. The tilting and locking of the arbor is accomplished through the medium of a hand-wheel. A second hand-wheel is employed to raise, lower, and lock the table. The motor is mounted on the saw arbor which is in turn mounted in a sliding bracket, which is supported by a yoke. The yoke is hinged to the housing. The motor has a speed of 3,600 r. p. m. and is controlled by an enclosed safety switch mounted on the outside of the housing. A complete set of graduated switches forms part of the regular equipment. The saw is manufactured by the Tannewitz Works of Grand Rapids, Mich.

ADJUSTABLE BORING BARS

A new line of adjustable boring bars has recently made its appearance, in which the principle of scroll adjustment has been employed. The bars have been designed for rough boring, finish boring, reaming and line reaming operations. Several combinations of standard cutters may be included in one bar for boring to different diameters, counterboring and facing in one operation. By the combination of angle and straight cutters several sets can be spaced close together on a bar. The thread of the scroll engages curved teeth which are located on one side of the cutters. The scroll is revolved by placing a wrench in a square hole located at its centre. Graduations on the scroll permit of accurate settings to be made. There are also provided two locking screws that are used to keep the cutters in position after setting. The inner ends of the cutters overlap each other which permits of greater expansion and rigidity. The cutters are backed metal to metal and it is practically impossible for them to work loose. The design of the angle cutters, coupled with the method of adjusting them both radically and longitudinally, makes them particularly well adapted to counter-boring operations. The faces of the cutters can be ground after they have been set, which enables them to be always kept in their original relative positions. The angle cutter also lends itself nicely to the boring of blind holes. With a combination of straight and angular cutters adjusted to a common diameter, a four point boring or reaming tool can be obtained. Cutters can be removed from, and replaced in the bar without taking the bar out of the machine. A number of designs of this type of bar are being manufactured together with accessories such as pilots, extra and special cutters, etc. The bars are manufactured by the Hannifin Mfg. Co., of Chicago, Ill.

DOUBLE-HEAD HOLE GRINDER

A semi-automatic double-head hole grinder has receently been placed on the market. This machine was primarily designed for finishing wrist-pin holes in internal combustion engine pistons, but may be adapted for double grinding of holes on which hubs, cluster gears, bearing cages, and other similar work where concentric holes are required on opposite ends of the same piece that is within the range of the machine. Both holes are ground at the same time, with only one setting of the work, and the dressing of the wheels assures duplication in size of both ground holes, and in accurate alignment no evidence of bell-mouth appears in the holes. The chuck has a range, for piston work, 4½ in. dia. by 4½ in. long. For other work the dia. may be increased to 6 in. Work revolves at 250 r. p. m. Wheel spindle drive shafts are mounted in ball bearings of enclosed type. The machine occupies a floor space of 3 ft. by 7 ft. and weighs about 2,300 lbs. The machine is manufactured by the Bryant Chucking Grinder Co. of Springfield, Vt.

BACK-FACING ATTACHMENT

A universal back-facing attachment that is power operated has recently been applied to an engine lathe. The attachment is particularly adapted for the turning of bevel gears. It is a simple matter to set the device for machining the gear at any desired angle, and the bevelled surfaces can be machined simultaneously with the turning of the gear hubs. Nine in-feeds are obtainable, ranging from .003 in. to .050 in. per spindle revolution. The feeds are secured through gearing connected to a splined shaft at the rear of the machine. Reversal of the mechanism is accomplished by sliding positive clutches which engage with worm gearing. There are twenty-seven automatic reverse feeds,

ranging from three to fifteen times the forward feed that happens to be engaged. These feeds enable the operator to secure the proper timing necessary for back-facing, necking, undercutting, and grooving work. The infeed stop causes the mechanism to reverse automatically while the out-feed also stops automatically at the completion of a cycle. The relation of the back-facing feeds to the turning and facing feeds of the lathe permits innumerable combinations and puts the lathe into the semi-automatic class, because when equipped with this device, several machines may be run by one operator. The lathe and attachment are made by the Seneca Falls Mfg. Co., of Seneca Falls, N. Y. The lathe is marketed under the trade name of the "Adams Short Cut" lathe.

TURRET LATHE ATTACHMENT

Automobile manufacturers have been faced with a trying problem in endeavoring to rapidly turn forged bevel gear blanks, owing to the special metal that was in these blanks. To facilitate such operations an attachment has been brought out by a manufacturer of turret lathes which enables a higher production to be maintained. The attachment has tool slides and one of these interchanges with the top slide of the regular carriage, so that the machine may be used either for bevel gears or for the other classes of work regularly handled on the turret lathe. The attachment is suitable for machining work up to 14 inches in diameter, and to all standard angles. The two tool slides are operated by the hexagon turret and the saddle and they work simultaneously. Racks and pinions are the mediums used to operate the slides. The attachment is manufactured by the Warner & Swasey Co., of Cleveland, O., and fits their regular No. 3-A hollow hexagon turret lathe.

DOWN-STROKE GEAR SHAPER

Recently a gear shaper that had been marketed in only the up-stroke design has been developed in the down-stroke type and has made its appearance in several sizes. The teeth are cut on the down-stroke and the tool head is placed beneath the ram. The ram can be elevated by power to a sufficient height to enable an arbor filled with gear blanks to be inserted in the machine. The tapered arbor is drawn into the socket, and ejected from same at the completion of the operation, by power. The machine is electrically driven throughout, and is started and stopped by a push button. The machine is manufactured by the Stevenson Gear Co., of Indianapolis, Ind. It is very similar, in many ways, to the up-stroke machine put out by this firm some months ago. The new machine, however, has a wider range of adaptability. Cutting tools are interchangeable with the older machine. A number of sizes of the new machine are being built.

UNIVERSAL SHAPING SAW

A machine that is one step ahead of a power hack saw has recently made its appearance. It has been designed along lines that adapt it for many operations impossible to perform with the ordinary hack saw machine. The machine tool principle of design enters into the construction. The saw blade is carried in a four-sided frame which permits ample tension being applied to the blade without fear of distortion in the bearings. The saw frame is supported on the horizontal bearings or ways of a vertical slide, which, in turn is mounted on vertical ways on the main frame of the machine. The saw frame is reciprocated through a crank and connecting rod mechanism. A quick-return motion is incorporated in the design. A speed box having a cone of gears provides three changes of cutting speeds. A positive adjustable power feed mechanism is provided, and also on the return stroke the saw blade is lifted free of the work. An automatic feed regulator is provided. If hard spots are encountered the feed is correspondingly reduced. But if the metal is homogeneous, a positive and regular feed is maintained. When a cut is completed the feed worm is automatically disengaged, and after this a spring lifts the saw frame to its upper position and stops the machine.

For the performance of angle-cutting operations, a special fixture is furnished on which the work may be clamped to either a horizontal or vertical face. Another convenient feature which adds to the usefulness of the machine is a cross feed mechanism secured to the table. A piece of work can be placed in this fixture and fed transversely under the reciprocating action of the saw, the latter acting like a shaper tool and producing a smooth finish on the surface machined. A cooling system is provided. The machine has a capacity for work 6⅝ inches square, takes blades from 10 to 14 inches in length and has a stroke of 5½ inches. The maximum number of strokes per minute is 132 and the minimum 50. When equipped with a standard vise the machine weighs 750 pounds. The saw is manufactured by the Peerless Machine Co., of Racine, Wis.

COMBINATION BENCH MACHINE

A combination bench lathe, for ordinary lathe work, drilling and milling has recently been developed and placed on the market. The base and column have the ear marks of a radial drilling machine equipped with a floor plate. The lower part of the column is circular and fully machined. The upper part is a segment of a circle with ways, along which a head, carrying the spindle slides. The spindle can be set horizontally or vertically, or at any point between these limiting positions. A knee with a double deck tool slide on its upper machined surface, is clamped to the circular column and operates very similarly to that of a milling machine table. An outer support, which is removable, can be arranged to support the outer end of the knee or table. It extends above this point and can be used as an outer support to the spindle of the machine, when used as a plain horizontal milling machine, or as the tail centre of the machine when used as a lathe.

Vertical milling can be accomplished by placing the spindle in a vertical position. End milling can thus be accomplished at any angle from 0 to 90 degrees from the horizontal. Drilling can be accomplished by inserting the drill chuck in the spindle and this operation can be taken care of at any angle. The table can be swung to one side and the outer support removed, allowing large work to come under the spindle, for drilling. For lathe work the spindle is in a horizontal position and face plate, collet, or chuck, may be attached. The tail centre is provided by the outer support. The table becomes the bed and ways of the machine, and the main tool slide, the carriage and the saddle. The top tool block becomes the cross slide.

The machine is motor driven by a ¼ h.p. motor mounted in the spindle housing and driving the spindle through the medium of a belt on a top step cone. Thus the drive is always in the same relative position to the spindle. The motor is reversible, and right or left hand tools can be used. There is a final three speed gear drive to the spindle. Thus six spindle speeds are obtainable, varying between 90 r.p.m. and 1150 r.p.m. The head is counter-balanced, and the spindle has a feed of three inches. All feeds are by hand except when it is desired to cut threads, automatic feeding being provided in this instance.

All parts of the machine are graduated, and a Jacobs drill chuck, having capacity up to ½ inch is regularly supplied. Some of the specifications of machine are as follows: Longitudinal feed of carriage, 10 inches; transverse feed of carriage slide, 6 inches; vertical feed of bed, 4½ inches; maximum swing over carriage, 8 inches; maximum swing over bed, 14½ inches; maximum centre distance, 14 inches; maximum height with spindle in vertical position, 43 inches; weight of machine, about 450 pounds; and bench space required 16 inches x 25 inches. These machines are manufactured by the Triplex Machine Tool Corp. of New York.

Gould and Eberhardt of Newark, N. J., have just received from the printers a folder that illustrates and describes in an interesting manner the many features of their shapers.

* * * *

The Oliver Machinery Co. of Grand Rapids, Mich., are distributing a bulletin which illustrates and describes their lines of circular sawing machines, and the care of the same.

* * * *

The Black and Decker Mfg. Co. of Baltimore, Ind., are distributing a small catalogue, covering their line of portable electric tools, which include electric drills, screw drivers, socket wrenches, grinders, safety cleaning machines and valve grinders.

Things Look Brighter

GENERAL business is on the upgrade. The improvement may seem slow to those longing for a return to normal, but a slow and steady improvement is preferable to an ephemeral boom which only results in a further setback. The steel trade in Canada is picking up slowly but steadily and with the season opening up we can look for further improvement in this field.

Residence building is strengthening, and several public buildings, roads and bridges are either being contemplated, or are in course of erection. The machine tool trade, while still quiet, shows signs of strength and confidence, so that even this line can be expected to record a fair amount of improvement as the year proceeds.

To a great extent, conditions in the United States reflect in due course of time on Canada, and the latest business reports from the former country say that the activity in building operations is an outstanding feature at the present time. As building in that country ranks second to agriculture, many million workmen are directly or indirectly dependent upon it. Many other lines show increased activity, and there appears to have been some decrease in industrial unemployment.

Unfortunately there still exists in both countries disturbing factors which militate against further improvement, high labor charges, high transportation rates and strikes being the chief trouble-makers. To clear up these difficulties will take time, but all things considered, the period of depression and discouragement is safely passed, and there is good cause for confidence in the future.

A Disgraceful Suggestion

"CUT DOWN production to a point where all profits vanish." This, briefly, is the suggestion made by J. B. McLachlan, secretary of the United Mine Workers of America, to the mine workers in the Nova Scotia district.

Mr. McLachlan not only admits publicly that he made this suggestion, but he claims to see nothing dishonest about it. In fact, he says that this traffic, as a method of retaliation, is a good one. He openly defies the minister of labor, and remarks that he will continue to preach this doctrine, knowing that the miner has a perfect right to work with his coat on if he wants to. He proudly points to the fact that previous to the reduction in wages, a certain mine produced coal at a labor cost of $2.02 per ton, but that since the wage cut, the labor cost of coal production has increased to $2.25. Concluding, he remarks that "add the overhead charges on that miserable tonnage of coal, and you may be able to guess why the miners are singing as they fight against the unjust wage."

It is time these highly paid agitators were made to understand that there are limits to freedom of speech. A suggestion such as this man makes fairly reeks of anarchism. True Canadians will not tolerate this policy for it is dishonest to work for a full day's wage, giving in return only partial and grudging service.

Apart altogether from the recent wage reduction and dealing only with the point at issue, viz., the question of a fair day's work, it is to be regretted that by a vote of four to three the executive board of district 26 have adopted this disgraceful suggestion, calling upon the 12,000 miners of Nova Scotia to cut coal production to the profit-vanishing point. Already several men have been discharged for loafing, and the mine-owners should take a decided stand in this matter. It is to be hoped that Canadian common sense will override the new policy and that the Canadian miners will turn down this diabolical suggestion and see that it is to their own interests to give a fair day's work for a fair day's pay.

Good Things Are Ahead

GOOD THINGS are ahead for our readers during the next four weeks. On April 6th we will have a story on the "Small Job and How Profit Can be Made on it," while in the April 13th number we start a most important series by an expert on "Lighting as a Manufacturing Asset." The following week the question of "Vertical Milling" will be discussed showing how money can be saved, while in the last issue in April we will tell of "Inspection Methods Which Have Proved Successful." Altogether a good month and one which readers cannot afford to miss. Watch for these articles and if the renewal of your subscription is about due be sure to renew.

* * * *

Will It Benefit The Workers?

CONSIDERABLE interest has been aroused in manufacturing circles by Ford's latest five day work schedule. The daily papers as usual rushed around haphazard asking offhand opinions regarding the feasibility of the new scheme. The result was that none of the opinions published showed anything vital to base judgment upon.

From Ford's point of view it may be all right, but to adopt the same principle to the average manufacturing plant is practically impossible. In the Ford plant, in fact, in any highly specialized factory, the workers are almost machines in themselves. Machinery speeds up production, and it is an altogether different proposition from machine tool building or general manufacturing. The Saturday afternoon off is a mighty good thing for any plant and a man needs this time for home duties and home life, but there is such a thing as having too much leisure.

If every Ford employe took advantage of the extra time given to better himself, then something of a really creditable nature would result, but for every one that devotes his added time to study, there will be ten who will take the opportunity to go joy riding or visit the many places of amusement. Should the employes all suddenly decide to study for better positions, Ford would soon have a new problem on his hands. After all is figured out, five days at the minimum wage of six dollars, is only $30. If a vote were taken among the workers themselves, it is more than likely they would favor the six day ruling with the added weekly wage. Money as well as leisure is essential, if home comforts are to be secured.

Iron and Steel Demand Shows Slight Increase

Prices on Steel Have Stiffened—Small Tools and Supplies are Selling at a Fairly Good Rate—Scrap Metals and Pig Iron Are Dull—Other Lines Merely Holding Their Own

MARCH SHOULD SHOW UP AS GOOD MONTH

COMPARING March business with that of last month there is a steady upward tendency on the Canadian market which cannot be ignored. Some branches show a greater gain than others, while a few sections merely hold their own.

The demand for pumping machinery has increased 25 per cent. over the corresponding period of last year, and using this same comparison, here is how other lines stand. Railway equipment and tractor supplies 25 per cent. increase, pipe fittings and valves 10 per cent increase, machine tools about 40 per cent. decrease, and machine shop supplies 10 per cent. increase.

Pig iron is still down, and scrap metals also remain weak. Boiler tubes and blue annealed sheets are in good demand, and an average amount of seasonable business exists in all other iron and steel lines. Orders are coming in more freely and are easier to secure, as manufacturers seem to have allowed their stocks to get to the low point. The average business closed is for immediate delivery and prices are stiffening all round. Dealers feel that the total business closed this month will exceed February by at least 10 per cent. Several good orders have been secured during the week, but no increase in quotations has taken place.

Larger discounts are being offered in wrought iron nipples these coming into effect immediately.

The small tool and supply business has picked up quite a bit during the week and one dealer reports more business during this week than any other similar period within the last six months. Several dealers felt sure that March business would be below the February mark, but an influx of orders during the last seven days has changed the situation so that an increase of at least 10 per cent. is expected.

Machine tools are much about the same, and no gain over last month is expected. Steel pipe is strengthening, and makers of this commodity have advised users that owing to orders on hand at the mills, they should place their requirements at as early a date as possible in order to secure service.

Oils, greases, and waste are in fair demand, no price changes having taken place in any of these lines.

Steel prices in the United States remain firm, and bars, shapes and plates show the greatest stiffening tendency. At present quotations range from $1.40 to $1.45 but there is quite a bit of talk to the effect that $1.50 will be the rate within the next week or two.

Wire nails are firmer and the sheet market is stiffening. One firm announces an advance of $3 per ton commencing April 1. Tubular goods are still being shaded, while tin plate remains steady. Steel ingot production is between 29,000,000 and 30,000,000 tons, which shows there has been no material change during the last month.

Furnace coke is firmer, $3.50 flat being the price for spot or prompt. Demand is rather light, but foundry coke is in slightly better demand and continues at $4.25 to $4.75 depending on brand. Pig iron is firmer and buying is light, although a slight improvement has made itself felt during the week.

Toronto

March 29

TAKING everything into consideration, March, locally, will show itself a better month than February. Some of the improvement which has occurred has been seasonal, but in other fields the upward trend has been a slow but gradual process since the start of the year.

Iron and Steel:—This branch of the trade has shown a steady gain during the month, and in the past week a decided tone for the better has made itself felt. Boiler tubes and blue annealed sheets are decidedly active, while other lines such as bars, small shapes, etc., are all moving at a fairly good rate. Orders for iron and steel goods are coming much easier, and there is not so much bickering about prices. In fact, all prices are stiffening, and while there has been no advance, there is some talk of a slight increase. Should the United States Steel Corporation put their price up to $1.50, it is almost certain local quotations would go up in sympathy. The orders being received are from a very scattered territory, which is a healthy sign. To show how business is picking up, we know of one salesman who secured orders for over 750 tons in less than a day, and without any sensational effort.

The annual report of the Steel Co. of Canada shows that while the surplus was drawn on to meet dividends, the company is in good shape in spite of the depression period they have been passing through. Even Mr. Hobson, the president, is satisfied with the showing, and while he refuses to voice any opinion regarding the outlook for the current year, he feels that business is improving, and that in all probability a moderate uptrend will continue. The new alloy steel company which may be located in Sarnia is discussed in another column. Following are present quotations:

Iron bars	2 75
Steel bars	2 75
Reinforcing bars	2 75
Steel hoops	3 75
Tire steel	3 00
Spring steel	6 00
Band steel, No. 10 gauge and 3-16 in. base	3 25
Small shapes	3 00

Pig Iron:—The demand for pig iron remains very light with little chance of immediate improvement. Prices are unchanged, $21.75 being the figure quoted on ordinary business. Foundries refuse to stock up until they see orders ahead, and as this is impossible at present, things must remain quiet. Another two months should see a slight improvement at least, according to several interested.

Non-Ferrous Metals:—No improvement can be reported in this section. Demand is still light, and there is no sense in altering prices for even such a move would have no results. Following are present quotations:

Lake Copper	17 00
Electric Copper	17 00
Castings, copper	16 50
Tin	34 00
Spelter	7 25
Lead	6 75
Antimony	8 00
Aluminum	26 00

Scrap Metals:—The demand in some lines is picking up slightly, cast iron borings and mixed turnings being featured. This material is being sold to outside points, but the margin of profit is very low owing to high freight rates. In many cases the freight cost is the highest item of all. As far as other lines of scrap are concerned, a certain amount of material is moving, but nothing to elaborate on. Following are present prices:

Copper, light per 10 0lbs.	8 00
Copper, crucible	10 50
Copper, heavy	10 50
Copper wire	10 50
No. 1 composition	8 50
New brass cuttings	6 00
Red brass turnings	6 00
Yellow brass turnings	4 75
Light brass	3 50
Medium brass	4 50
Scrap zinc	3 25
Heavy lead	4 00
Tea lead	3 00
Aluminum	10 00
Boiler plate, per gross ton	9 00
Heavy melting steel	10 00
Axles (wrought iron)	16 00
Rails (scrap)	10 00
Malleable	11 00
No. 1 machine cast iron	15 00
Pipe, wrought	6 00
Car wheel	16 00
Steel axes	15 00
Mach. shop turnings	6 00
Stove plate	14 00
Cast boring	5 00

Machine Tools:—The demand for all sorts of machine tools remains much the same. Several dealers may have an extra good week, while others recede a little. Taking an average, February and March will be about equal. Compared with the corresponding period last year, present business would be about 40 per cent. lower. Pumping machinery

shows an increase over last year of 25 per cent., while railway equipment and tractor supplies are up a similar amount.

Small Tools and Supplies:—Owing to the good business received during the week, dealers have a better story to tell than expected. It now looks as if March will show a 10 per cent. increase over February, and low stocks held by manufacturers seem to be the answer. One dealer told Canadian Machinery that he received more orders last week than he has done in any week during the last six months. Of course this cannot continue at such a rate, but averaging up the months since the start of the year, a steady upward trend can be noted. Pipe fittings, valves, etc., show a 10 per cent. increase over last month, so that in this field also an improvement was felt.

Steel Pipe:—This market is finding a good demand. In fact one mill has notified its customers that owing to the present orders on hand they suggest that firms requiring steel pipe place their requirements at as early a date as possible in order to secure service and protection. Prices remain firm.

Miscellaneous:—Oils, greases, and waste are in fair demand and there has been no changes in call or price during the week. The automotive trade is responsible for some of the betterment in several lines, but owing to lack of funds, the railways have not yet entered the market.

Montreal

March 29.

REPORTS FROM various sources regarding volume of business offering locally are varied and conflicting. However, in no instance does it appear that the past week fell below the previous one. The points along which reports differ seem to be in the amount of increased business, but no particular article is in special demand. Local business men attribute the better trend of business to the natural seasonable demand, and they point out that in a climate as rigorous as ours, certain activities are bound to be held up during the winter months, and that lack of activity in certain lines in the winter months is not a positive indication of the situation from a business point of view.

The centre of spring activity is still along the waterfront. In addition to the ordinary work of fitting out shore and floating equipment, there are several new buildings and quite a lot of new equipment that will be in use for the first time this spring. The Grand Trunk is increasing its elevator capacity and the Harbor Commissioners are rushing to completion their new cold storage warehouse, etc. In the local elevators there is a large quantity of grain awaiting overseas shipment. In fact there is every reason to believe that the record business of 1921, that passed through the Port of Montreal, will at least be equalled, if not exceeded in 1922.

Iron and Steel.—Several firms report that all lines have been moving more freely this week than last. Inquiries have been coming in more freely and office staffs are busier than they have been in some weeks, taking care of orders and prospective business. Throughout the Island of Montreal building activities are most marked. A large proportion of this building is to relieve the housing shortage, but there is sufficient building of a large nature, such as factory extensions, warehouses, office buildings, etc., to create an increased demand for structural steel. Reinforcing bars are moving more freely, and most of this business is being received from contractors and contracting companies. Firms such as the Dominion Bridge Co. claim they are figuring on a reasonably large number of jobs, but that only a few are expected to turn into real business. For the first time in many months the demand for merchant bars is making itself felt. This line has been practically dead for the best part of a year. The connection with British firms has not yet been reestablished, as prior to the war a great percentage of the merchant bars handled locally were imported from British mills. These quotations have not been as low as the American for some time past, and for that reason all bars produced outside the country that are handled locally are of United States manufacture.

Sheets and plates are still moving, and the only steel product imported from British mills to any great extent is galvanized sheets. Prices in all lines are firm. No actual advances have been made, but conditions in the States are being closely observed. The independent mills have agreed to a base price of $1.40 but some are agitating for a further increase to $1.50. The United States Steel Corporation is not increasing prices, up to the figure that the independents have agreed to maintain, but they have shown that they are in sympathy with a rising price. These factors are having a definite influence on local quotations, and there is every indication that the present firm prices will be revised upward in the near future. Most jobbers and dealers are not carrying heavy stocks, therefore any further increased mill quotations will be promptly reflected locally. The present quotations are as follows:

Iron bars	2 75
Steel bars	2 75
Reinforcing bars	2 75
Steel hoops	3 75
Tire steel	3 00
Spring steel	6 00
Band steel, No. 10 gauge and 3-16 in. base	3 25
Small shapes	3 00

Pig Iron.—The pig iron situation is not at all satisfactory from the producers' point of view. Quotations for No. 1 iron, 2.25 to 2.75 Silicon, rule at $29.80. United States conditions have a very definite influence with this commodity, and although it has been definitely determined that the cost of producing pig iron at Buffalo is from $21 to $23, yet the prices asked run from $18 to $18.50. It is illegal to import goods into Canada that are invoiced below producers' cost plus a fair profit. Thus pig should not be shipped into Canada at Buffalo quotations, but nevertheless iron is coming into the country. Some firms, with international connections, flatly state they cannot comply with recent Canadian Customs regulations and will not accept Canadian business. At present local quotations the Canadian firms are said to be losing money. The demand has fallen off a little during the week, and there is no immediate chance of any improvement in the near future. Foundries do not look forward to anything but a nominal increase in business, so that present quotations will no doubt be maintained.

Machine Tools and Supplies.—A little better demand is evident in the machine tool field, but dealers are not satisfied with the present volume of business. Recent price reductions have had the effect of interesting a larger number of prospects, but it is still difficult to close business. Supplies are somewhat improved. Quite a volume of repair work is being given out and contract shops are coming into the market for supplies in a more satisfactory manner. There are no radical price changes, and orders are being aggressively sought.

Non-Ferrous Metals. — Very little change has occurred in the non-ferrous metal market. No change in price has been made, and the small demand for the past few weeks is just about holding its own. Local quotations are:

Lake Copper	16 75
Electric Copper	16 50
Castings, Copper	16 25
Tin	34 00
Spelter	7 00
Lead	6 50
Antimony	6 50
Aluminum	23 00

Scrap Metals.—A slightly better tone in the scrap metal market is evident. Prices are not changed. Contract shops are responsible for the increased demand, but this is not large enough to influence the market.

Copper, light ..... per 100 lbs.	8 00
Copper, crucible	10 50
Copper, heavy	10 50
Copper wire	10 50
No. 1 composition	8 50
New brass cuttings	6 00
Red brass turnings	6 00
Yellow brass turnings	4 75
Light brass	3 50
Medium brass	4 50
Scrap zinc	3 25
Heavy lead	4 00
Tea lead	3 00
Aluminum	10 00
Boiler plate, per gross ton	9 00
Heavy melting steel	9 00
Axles (wrought iron)	17 00
Rails (scrap)	10 00
Malleable	10 00
No. 1 machine cast iron	18 00
Pipe, wrought	7 00
Car wheel	18 00
Steel axes	16 00
Mach. shop turnings	4 00
Stove plate	16 00
Cast boring	3 00

Pittsburg

March 29.

PITTSBURG.—(Special to Canadian Machinery.)—Enough time has not elapsed since the last softening in price of any steel product to make it clear

that the long decline in prices has ended. Prices may decline any number of times in the future history of the steel industry, but this one decline is over. Steel prices are now stiffening, rather than advancing, but the stiffening is likely to merge into actual advances of greater or less importance. Bars, shapes and plates, which led the decline, and went farther relative to cost of production than any other steel commodity, show the greatest stiffening. In the past fortnight or so 1.40c has been the minimum of the market, whereas for awhile this price was shaded in numerous cases by $1 to $2 a ton, perhaps a trifle more in some cases. In the past week the less desirable orders, including carloads, have been going largely at 1.45 and 1.50c. Predictions are freely made that in a short time, perhaps a week or two, the minimum of the market will be 1.50c. The mills are very anxious to get the price up at least to the price of production, though at the same time they are anxious to book all the tonnage they can.

In wire nails the price situation is much improved from the mill standpoint. A month ago, shortly after the market had declined to $2.40, shading of this price developed and it appears that almost all large buyers were able to get concessions down to $2.30 or even $2.25. In the past three weeks there has been no shading at all in evidence, the market being firm at $2.40.

Sheets Improve.—On the surface at least the sheet market looks stronger. That is, the Wheelin Steel Products Co., announced on March 22, that on April 1, its prices would be advanced $3 a ton, and the trade has been looking for other producers to make somewhat similar announcements. However, it is not certain that such episodes really prove the sheet situation to be stronger, for in some quarters it is said that the mills in general are booking little business at current prices and announcements of advances to be made in future may have as their chief object the driving in of business at current prices.

In tubular goods there is shading still, but there is no evidence that the shading is greater than a month ago, and it may be somewhat less. In tin plate there is a very steady market. large lots going at $4.60 and small lots at $4.75.

From the points mentioned, and other considerations, it is plain that the decline has ended and steel prices are in general presenting a stiffening tendency. It is out of the question, of course, for there to be any large advance. Before the war it was held that steel prices could not advance to any extent if mill operations were at under 85 per cent., while the operation now is about 55 per cent. and the most sanguine estimate is that the rate will be up to 70 per cent. by June 1. Small advances, to get prices up to the full cost of production, are another matter.

The Future of Demand.—There is much more divergence of opinion as to the future of the steel market than there has been at any time for a long while. The lines of division are clear cut. The difference is not as to the actual facts so much as to the interpretation of the facts. Some assert that steel demand will continue to increase, because it has been increasing since the first of the year and spring has now arrived. Others assert that the increase in demand lately has not been in keeping with the general industrial and financial situation and claim part of the buying has been for replenishment of stocks, hence does not need to be done over again. Some observers with long experience contend that it is plain the country is not actually consuming steel at the rate at which deliveries from mills are being taken.

April will undoubtedly tell which party is right. If there has been much stocking, part of it at least has been prompted by fear that after April 1, on account of the union walkout at the bituminous coal mines, the production and shipment of steel might be interfered with. Such buyers would not take steel with equal freedom in April. As a matter of fact it is entirely improbable that the coal strike will have any direct influence in curtailing mill or railroad operations. The continued softening in the coal market in the past three weeks, with lighter and lighter demand, shows that consumers are satisfied with their stocks of coal, and there is no reason to suppose they have underrated the strength of the walkout, which has been very well advertised for months past. There is direct testimony as to the steel mills, that they have good stocks of coal, while there are likely to be fairly heavy shipments from the Connellsville and other non-union regions.

On the whole there has been no material change in the general rate on mill operation, though some lines are doing a little better and others not as well. Current estimates are that the rate of steel ingot production is between 29,000,000 and 30,000,000 tons a year, which would mean that there has been no material change for four weeks. From January 1 until about four weeks ago the rate was rising rapidly. However, the Carnegie Steel Co. recently announced that it would blow in six more blast furnaces by April 1, giving it 35 in operation out of 59, and that would make quite a change though of course there may be decreases elsewhere.

Connellsville furnace coke is quotable higher, at $3.50 flat for spot or prompt. Demand has been light in the past week, but previously there was good absorption, taking up all coke offered at under $3.50, some of it at down to $3.25. Between 400 and 500 additional merchant ovens are going in, largely perhaps because the coke market looks so promising while it has been increasingly difficult of late to sell coal. Foundry coke continues in good demand at former prices, $4.25 to $4.75, depending on the brand.

The pig iron market seems quite firm now, with prices stiffly maintained at $19.50 for Bessemer, $18 for basic, and $19 for foundry, f.o.b. valley furnaces, freight to Pittsburg being $1.96. Buying is rather light, but seems to have improved somewhat, while shipping instructions against old contracts are better. Predictions continue that Lake Superior iron ore prices will be down about a dollar a ton, f.o.b. Lake Erie docks, for the 1922 season, following the dollar decline for last season, but no early action in the market is expected.

EXPECT ANNOUNCEMENT OF MACHINE TOOL MERGER

Plans have almost been completed for the amalgamation of a number of machine tool manufacturing companies in the States. Details are now being arranged. The companies mentioned are the Betts Machine Company of Rochester, N. Y. The Colburn Machine Tool Co., Cleveland; the Newton Machine Tool Works, Philadelphia; the Modern Grinder Manufacturing Company, Erie, Pa.; the Carlton Machine Company, Cincinnati; the Lodge & Ship Machine Tool Company, Cincinnati and Hilles & Jones Company, Wilmington, Del. In addition to those mentioned several other companies are involved. The new corporation will lean particularly toward the manufacture of equipment for railroads, at the same time turning out a fairly complete line of machine tools for all purposes. It is thought the American Locomotive Co., is behind the movement.

NEW PLANT IS PLANNED

The Dominion Alloy Steel Corporation has been incorporated with an authorized capital of $15,000,000. The intention is to establish a plant at Sarnia, Ont., and undertake the production of alloy steel in Canada. Among the men interested are Geo. A. Simpson, sales manager and special representative of the Steel Co., of Canada; Harry R. Jones, president of the United Alloy Corporation, Canton, Ohio; C. Harold Wills, president of the C. H. Wills Motor Co.; J. J. Mahon, formerly chief engineer of the Crucible Steel Co. of America; Sir. Wm. Mackenzie, Toronto; Wallace Jones, Toronto, and others.

Reports published to the effect that Sir Frederick Becker, representing an English syndicate, is negotiating for the purchase of a large percentage of the pulp output of the Riordon Co., Kipawa Mill, were declared by officials of the Riordon Company, to have been unfounded. In denying the truth of this rumor, A. W. Killam, pointed out that a very vital reason why the Kipawa Mill would not be likely to enter the overseas export business, lies in its geographical position in relation to the seaboard. Mr. Killam further stated that under normal conditions, the established clientele of the Riordon company would require the entire pulp output of the mill in question for the manufacture of high-class papers and artificial silk. He also stated that the Kipawa plant had been running from half to full capacity all this year, and that at the present it is running at capacity.

SELECTED MARKET QUOTATIONS

Being a record of prices current on raw and finished material entering into the manufacture of mechanical and general engineering products.

PIG IRON

Toronto price:—	
Silicon, 2.25% to 2.75%	27 15
Grey forge, Pittsburgh	$19 00
Lake Superior, charcoal, Chicago	30 00

News From the Industrial Field

The Timkin Roller Bearing Co., have taken a floor in the Walker building, Walkerville, Ont.

The Universal Wrench Co. of Windsor, Ont., plans to move its plant to Amherstburg, Ont.

Tudhope & Ludgate, Parry Sound, Ont., is in the market for equipment for a proposed saw mill at Deer Lake, Ont.

The United Auto Supplies Ltd., Montreal, is in the market for machine tools and lathes for general auto repairs.

The Air Reduction Co., have purchased all assets, trademarks, including patents and trade names of the Davis-Bournonville Co., Newark, N. J.

The Goderich Salt Co., Goderich, Ont is in the market for special salt handling equipment and additional equipment to double its capacity, estimated cost $30,000.

The article appearing in last week's issue on "Controlling the Cost of Labor and Output" was compiled from information obtained through the courtesy of the International Business Machines Co.

Canada's total imports last year were valued at $799,394,598 of which $123,-149,000 represented the United Kingdom and $555,308,193 the United States. The exports totalled $802,699,820.

The partnership between Edward Woods and A. Ouellette, of the Wood-Ouelette Machinery Co., Amherstburg, Ont., has been dissolved and in the future the business will be carried on by Mr. Woods.

The city council of Chicago, has designated the week from April 2nd to April 8th as Canadian week, to celebrate the 104th anniversary of Peace and uninterrupted social and business intercourse.

Leslie H. Taylor, formerly sales manager of the machine tool division of the Greenfield Tap and Die Corporation, at Greenfield, Mass., has resigned to accept a position as sales manager with the Williams Tool Corporation at Erie, Pa. The Canadian branch of the latter company is located at Brantford, Ont.

The Waterloo Board of Trade is making an active effort to bring another large foundry to the city. The foundry now employs 60 men and if brought to Waterloo it is the intention of the company to secure additional capital, double the capacity and give employment to over 100 hands.

The members of the Woodstock board of health have come to the conclusion that Woodstock, Ont., needs an incinerator for the disposal of its garbage. An incinerator to meet the city's needs would cost $38,500 and the city council will be asked to submit a by-law on the subject at the next municipal election.

Official figures of newsprint production show that in January and February of this year, Canadian mills produced 159,712 tons as compared with 135,125 tons of the similar period of 1921. Shipments stood even better, showing 164,-031 as against 128,935 tons a year ago.

In the event of restricted coal production in the States, as a result of the miners ceasing operations, it is expected that adequate supplies will be received from Britain to take care of Canada's needs. Inquiries are now being made in London freight circles as to rates on coal shipments to Canadian ports.

R. Hermer, president of the Sawyer-Massey Co., Hamilton, Ont., in commenting on the general conditions of the company, stated that the company's plant is being operated at about 50 per cent. of its capacity; efforts are now being centred on the manufacture of engines and road making machinery, the sale of which is encouraging.

During the month of February, according to the regular monthly statement of R. C. Coffey, manager of the Lake Shore Mill, Kirkland Lake, Ont., the mill reduced 1.961 tons of ore and produced $44,082. The mill ran 97.17 per cent. of the possible running time, and treated an average of 70 tons of ore daily. The grade of the ore continued high at $22.48 recovered from each ton treated.

A. G. Pounsford, manager of the Port Arthur division of the Provincial Paper Mills, has announced the actual commencement of work on the construction of a paper mill extension of the company's present plant. The extension is to be completed by May 1, 1923, and at an estimated cost of $1.500.000. The first contracts for machinery, for 700 tons of structural steel and for the building have been let.

The report of the E. W. Bliss Company of Brooklyn, shows a small increase in net profits in 1921. Its net earnings were $2,925,125 after payment of expenses. Federal taxes and inventory adjustments, or $9.28 a share earned on the 300,000 shares of its no par common stock. In 1920 its net profits were $2,376,338 or $7.53 a share. The company's surplus was increased from $18,925,133 in 1920 to $19,368,409.

Large additions will be made to the cold storage plant at Grimsby, Ont. For several seasons this warehouse has been operated under the direction of the Dominion Department of Agriculture as an experimental plant, but has been turned over to the Growers' Cold Storage and Ice Co. Under the new arrangement the capacity of the warehouse will be quadrupled, and improved refrigeration will be installed, as well as mechanical facilities for the manufacture of ice.

White and Henderson of Sudbury have just completed the installation of a pumping system for the water supply for the town of Sturgeon Falls.

George Valentine, vice-president of the Massey-Harris Co., has been appointed president of the Bain Wagon Co. The latter company is now controlled by the Massey-Harris Co.

Henry E. Brennan, recently mechanical superintendent of the British American Nickel Corporation at Nickelton, Ont., has become associated with the firm of White and Henderson of Sudbury, Ont.

Canada Illinois Tools, Ltd., 163-187 Dufferin St., Toronto, has been incorporated for the manufacture of hobs, milling cutters and small tools. Harold C. Smith, president of the Illinois Tool Works, Chicago, is president, R. L. Danielson, treasurer and assistant secretary, Donald J. Noble, secretary and J. D. Sherman, vice-president and managing director.

A statement just issued by the Dominion Bureau of Statistics shows that in 1919 there were 38,344 manufacturing establishments in Canada, with an invested capital of $3,230,686,368. At that time Ontario headed the provinces in the number of establishments, the total being 16,438; Quebec was second with 11,061.

More men are to be put to work almost at once on sections one and two of the Welland Canal, according to the contractor, who says dredging work will be resumed soon at Port Waller Harbor. The big dredge Sandy is to be taken over from Port Dalhousie and set at work soon. A big force of men will be needed. Mr. Porter said on sections one and two only a hundred or so men worked all winter.

A. B. Muddiman, assistant trade commissioner in London to the Canadian Government, has temporarily taken over the trade commissioner's office at Bristol, in succession to Norman Johnson. Mr. Muddiman has recently completed a tour of Canada and is therefore well informed as to the prevailing trade condition. Mr. Muddiman's brother, Alexander Phillips Muddiman, C.S.I. has the distinction of being the first president of the Indian Council of Trade.

Because of work upon industrial establishments, the building outlook in Brockville, Ont., is brighter than for some years past. The major work to be carried out this season will be the construction of the plant of the Eugene Phillips Electrical Works, which is moving from Montreal. The Bank of Toronto is about to commence the erection of new premises and there is a marked increase in the number of permits for the building of business and residential properties.

The new asphalt plant at Windsor will be ready for operation early this spring. The opening of this plant will mark a new era in the construction and upkeep of city streets, because it will mean the advent of sheet asphalt as a surface metal.

Employment is improving. At the beginning of February 1922, according to returns which will shortly be issued by the labor department, the percentage of unemployment in Canada among members of trade unions, stood at 13.9 as compared with 15.1 at the beginning of January, and 13.1 at the beginning of February 1921. According to reports received from over 6,000 employers, employment registered expansion during February, as compared with January, but the situation was somewhat less favorable during the corresponding period of last year.

Mr. Geo. Valentine, vice-president of the Massey Harris Co., who is in charge of the manufacturing, and a director of the company, was recently appointed president of the Bain Wagon Co., of Woodstock, Ont. The Bain Wagon Co. is controlled by the Massey-Harris Co. Mr. Valentine is a remarkably able manufacturer and one of the young captains of Canadian industry who has come forward rapidly in the past few years. It will not be necessary for Mr. Valentine to leave Toronto, according to a statement made by representatives of the Massey-Harris Co.

Sherbrooke, Que., weathered the storm of industrial depression in 1921 in excellent shape, and, so far from witnessing a falling off in production, saw new industries added to her total. Among these was an addition to the cotton mills representing an investment of $5,000,000; a plant to manufacture gloves, hosiery and underwear, capital $3,000,000; a plant to manufacture super heaters for locomotives, costing $250,000; extension to plant making pulp and paper machinery, costing $200,000; jewellery manufacturing establishment, costing $50,000; establishment for manufacturing piston rings, costing $25,000.

Robert J. Magor, president of the National Steel Car Corporation, while paying an inspection visit to the Canadian plant at Hamilton, spoke very encouragingly of the prospects for business in car repair and construction during the present year. Mr. Magor said he based his opinion on the fact that during the first two months of this year the larger railways of the United States had purchased no less than 50,000 cars, a number that was equal to the entire output of car building companies during 1907. Another encouraging fact as regards the immediate future was that the large number of idle freight cars in the United States was being rapidly absorbed. At present these idle cars had decreased to 50 per cent. of what they were a few months ago. This fact proved that business was improving. There were few if any idle cars during good times.

OBITUARY

Robert Patterson, for many years master mechanic of the G. T. R. shops in Stratford, died last week after a prolonged illness. Deceased was born in Brantford, 62 years ago and commenced his railway career as an apprentice in Montreal in 1874. He assumed the position of general foreman of the shops at Toronto in 1888, when the Grand Trunk took over the Northern and Northwestern Railway. In 1897, he was made general foreman of the shops at Port Huron, Mich., and the same year master mechanic of the Grand Trunk lines west of the St. Clair River. In February, 1893, he was transferred to Stratford and assumed the position of master mechanic, which he retained until 1917. In 1917, he was loaned from the Imperial Munitions Board to the General Car and Machinery Co., at Montmagny, Que., to re-organise the shell plant at that place.

The late Robert Patterson, formerly Master Mechanic of G.T.R. Stratford Shops.

A manufacturer's representative in Brisbane, Queensland, Australia, can give good business to manufacturers of gas taps for stoves and grillers, etc., and invites export price lists and all particulars. Quotations and samples of bolts and nuts are also invited, with C. I. F. prices and guarantees as to deliveries. Firms making cash box locks should send samples and prices and discounts of all grades of locks. Brush manufacturers not already represented may secure good business, and are invited to send quotations and samples of scrubbing, laundry and nail brushes. In this case an agency agreement would be required. (R 102 S)

A fair amount of industrial building in Welland is forecast by the Industrial Commissioner, B. J. McCormick. He specifies an addition to Empire Cotton Mills, a plant for the newly formed Welland Cotton Mills; a plant 400 ft. long for the production of seamless tubes by the L. R. Weeks Co.; an addition 400 ft. long to the Electric Steel and Metal plant. In addition to these four building enterprises that will be proceeded with inside the city, Mr. McCormick stated there were three proposals to construct plants outside the corporation limits, two of which would probably be closed before the end of March.

Fire of an unknown origin started in the basement of the Packard Electric Co., St. Catharines, Ont., on March 22, where a quantity of oil was stored. Six large completed transformers for the Hydro-Electric Commission were in the cellar which was flooded with water. Until the effect of the water on the transformers is known the damage can not be determined.

A contract for 8,500 tons of girder and high T-rails has been placed by the Toronto Transportation Commission. This order was secured by the Toronto office of United States Steel Products Co., and the price is stated to be very satisfactory for the purchasers. The above quantity will cover Commission's rail needs for the season. Delivery will be made in 1,000 ton lots at intervals as required until September. The business is placed subject to the provision of funds by city council. Tenders have been called for accessories and this additional business will probably be placed within a few days.

Little or no change in the operation of the steel industry in Canada in recent weeks is reported by W. F. Franz, president of the Algoma Steel Corporation who was in Toronto recently on his return from the regular monthly directors' meeting of the Lake Superior Corporation in New York. Mr. Franz stated that his company's plants were operating at about 60 per cent. of capacity, and while there were no new orders of importance immediately in sight, he had expectations that coming months would bring new orders and larger business. There was a distinct improvement in feeling, he said, among steel interests in New York, and the impression was general that the worst had been experienced and a gradual improvement could be looked for.

In an address recently James Cormack, of Ottawa, who has just been appointed junior trade commissioner to South Africa, stated that it was the business of the trade commissioner to report to Ottawa all possible opportunities for the sale of Canadian products in the countries in which he was stationed. The trade commissioner would also advise exporters on all questions having to do with packing and documentation of goods shipped to the country to which he was accredited. Another service that was performed for the Canadian manufacturer or producer by the trade commissioner was the introduction to him of persons who would be suitable to act as representatives of the Canadian enterprise in the other country.

IMPROVEMENT IN THE EAST

The Royal Trust Co., of Halifax, is receiving tenders for the Davison Lumber lands and equipment.

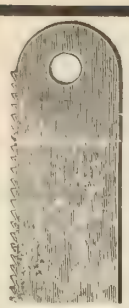
The Eastern Trust Co., of Halifax, is taking tenders for the Broughton Hardwood Products, Ltd., machinery and fixtures.

The Yarmouth, N. S. Light and Power Co., have an application before the Public Utilities Commission for permission for a $150,000 bond issue, the money to be expended on completion of the plant.

One of the old industries of Yarmouth, N. S., which has been dormant for twenty-six years, the Milton Iron Foundry, has been taken over by Yarmouth parties and started in operation.

Boring for oil is to commence at Bert McDonald's farm, Meadowville, Pictou County, N. S., the latter part of April. Pictou and Stellarton men are the promoters. A hole was sunk in the same vicinity some years ago, but was eventually abandoned.

The town of Truro, N. S., wants hydro electric power and the secretary and consulting engineer of the N. S. Power Commission will be there this week to look into the situation as to possibilities and requirements and attend a meeting of parties interested at the Truro civic building.



At the annual meeting of Thompson & Sutherland, Ltd., North Sydney, H. T. Sutherland was re-elected president and general manager, Henry McArel, vice-president, and W. S. Thompson secretary-treasurer. The company's foundry is at present working four days a week with a staff of about sixty, a third less than in normal times.

At this month's meeting at Sydney, of the Cape Breton branch of the Engineering Institute of Canada, S. C. Mifflen, A.M.E.I.C., read a paper on the operation and equipment of the iron ore mines at Bell Island, Newfoundland. On the island five distinct seams of iron ore crop up, but only three are known to be workable. Within the past year the Dominion Iron and Steel Co., put in commission a turbo-electric power station of over 3,000 horse power. The power house is built on the sea shore line and a pier for storing coal is built about it, the foundations being laid in 18 feet of water.

The dispute in connection with the development of power at St. Margarets Bay, near Halifax, has been settled, and the Tramways Company have commenced operations; excavations have been begun for concrete bases for a line of towers to carry the power from Armdale, a city suburb, where the receiving station had been built, to the Tramway's station, a distance of about a mile and a half, and large transformers are to be installed at the Tramway station. This station is at the south end of the city harbor front, and at the north end of the water front the Halifax Shipyards are installing transformers to handle the power coming to the plant from the Tramways. It is expected the power will be coming into use here next month.

The St. Thomas Packing Co., of St. Thomas, Ont., one of the most prominent packing companies of Western Ontario, has decided to erect at Welland, Ont., a storage plant for the handling of its rapidly growing business in the Niagara Peninsula. The company will put up the plant at a cost of $50,000 on a location, for convenience, near the city market, and three or four sites are under consideration.

The development of the power plant of Manitoba Power Co., it was stated at the annual meeting held in Winnipeg, is progressing very satisfactorily, over 500 men being employed on the works. The transmission line from the Winnipeg Electric Company's hydro-electric plant to the work, a distance of 17 miles, has been completed, and power is now being used in connection with the construction work. The orders for the hydraulic and electrical equipment have been placed. The turbines are being made by the Dominion Engineering Co. at Lachine, Que., and the generators by the Canadian General Electric Co. The switchboard and the Kingsbury bearings are being made by the Westinghouse Co.

SIMONDS

Non-Breaking

Hard Edge
Hack Saw Blades

When you put a Simonds Hard Edge Blade in your Hack Saw Frame you are assured of the maximum of cutting service, because these are the blades that cut fast, do not shell teeth, and when properly used they are non-breaking.

They are scientifically heat-treated and smoothly finished.

GETTING READY FOR INCREASED BUSINESS

"THERE is not much business moving in machine or wood-working tools at the present moment," according to R. M. Hamilton, works manager of the Canada Machinery Corporation, Galt, but this fact does not prevent Mr. Hamilton from displaying a good amount of sane optimism. He feels that things are bound to right themselves, and as he says, "we have in Canada one of the finest countries in the world. In fact the only country whose possibilities have not yet been fully discovered, therefore why should we be pessimistic?" Among many other things, Mr. Hamilton mentioned the gold mines which are now an established success in Canada, as compared with the present mining trouble in South Africa. "If we can successfully produce gold in Canada," he said, "we can likewise compete in other manufacturing lines with the markets of the world."

Continuing, he pointed out that while they had expected an improvement in wood working machine demand this spring, it had not developed as yet. He felt, however, that perhaps it was merely a little delayed, and that it would come along later on in the season. So far, although building of homes and furniture is improving, they have not felt any better tone, as wood-working factories were still taking up the slack. "Let building and furniture making continue," remarked Mr. Hamilton, "and in a short time we will be bound to feel the benefit."

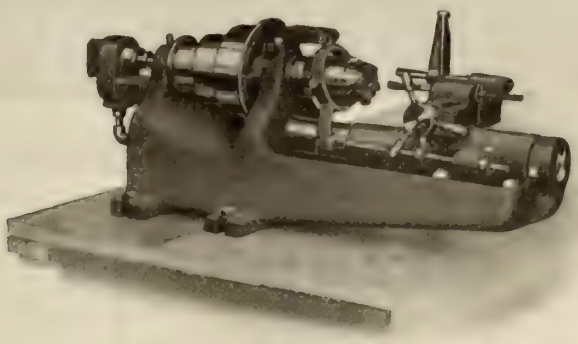
The Canada Machinery Corporation has been doing considerable development work recently, and speaking to Mr. Neill, sales manager of this concern, Canadian Machinery secured the following information:—Standard lines of wood working machines are rather slow just now, but special tools, are becoming in better demand, although usually only one, or a very few machines are required at a time. This involves a great amount of drafting and pattern work, and at present these two aforementioned departments are working 55 hours a week developing and designing new tools. Four new machines have been brought out this year, and more to follow. Among the special tools developed is a planer for planing the curves on school desk seats. Then there is a special planer and cutting machine for making battery box separators, this calling for very accurate work as the separators are made very thin. Briefly, the piece is 5/64 in. at the thickest portion and less than 1/32 in. at the thinnest point. Ribs occur about every ½ in., these being about 3/16 in. wide. It is a very difficult piece to make, and calls for careful design in the machine itself. Ball bearings form a part of the equipment, and incidentally, this firm is devoting a great deal of time to research work, planning the proper type of bearing to use for various purposes. They have also brought out a Ryerson friction saw, this machine carrying a saw 50 in. diameter. This is a high speed machine which is fully patented.

The chief feature, which impressed Canadian Machinery, is that this firm has absolute faith in Canada and its possibilities. They feel sure things are bound to pick up to normal again, and are directing every energy to getting ready for the improvement when it does arrive.

Oil Tempered
Steel Springs

for every purpose and the best for each use.

Special styles of all kinds to order.



THE CLEVELAND WIRE SPRING COMPANY

Cleveland, Ohio U.S.A.

STRENGTH IN STEEL IS LOOKED FOR

Without definitely committing himself, E. H. Gary, chairman of the U. S. Steel Corporation, intimated that there was a strong possibility of an increase in the price of steel products. He believed that the business trend at the present time was upward. Corporation plants are operating at about seventy per cent. of normal.

Mr. Kerr, of the Preston Woodworking Co., says that they are finding business as good as can be expected under the circumstances. He feels they are getting a good share of any orders that are going, and is firmly convinced that aggressive sales methods are essential to-day if work is to be secured. This firm is developing several new machines, and are embodying ball bearings as part of the equipment. Another feature on one machine being designed at present is a grinding attachment which permits the grinding of the knife blades without their removal from the cylinder. The roll feed on this same tool is made in sections, rather than in one piece, this guaranteeing that work being fed into the machine at any position on the table will be securely gripped.

ANOTHER GEOMETRIC LEADER

Brings Down Production Costs

The Geometric Bench Threading Machine is a wonder on small threaded work. It weighs but 90 pounds and takes bench space of only 9½″ x 29 inches. The 5/16″ Geometric Rotary Die Head with which the machine is fitted cuts threads of standard and finer pitch on diameters 1/16″ to 5/16″ inclusive. The machine is arranged for bolting to a bench, or it may be mounted on a separate pedestal for floor use.

AGENCIES WANTED

I WANT TO GET IN TOUCH WITH AN ENergetic young man who is very familiar with the metal-working trade in one of the larger cities in Canada. The work I want him for can be done in spare time—it is not altogether easy, such as "taking candy from a baby,' but with little effort he can double his income each week. Apply early to Box 803L, Canadian Machinery.

IF YOU ARE LOOKING FOR A HIGH-GRADE firm to handle through the hardware jobbers and consuming trade throughout the Dominion, write us. It will be worth your while to investigate the special features of our marketing proposition. We know what co-operation means. Write to Box 860T., Canadian Machinery.

BUSINESS CHANCES

WANTED—BY AN ESTABLISHED CONCERN. Twelve to fifteen thousand dollars for a period of from one to three years, to take care of business expansion. This concern will stand the fullest investigation. 8% is offered with ample security to principals only, with an opportunity of becoming permanent associates with the partners, if mutually satisfied. Box 767, Canadian Machinery. (etfm)

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

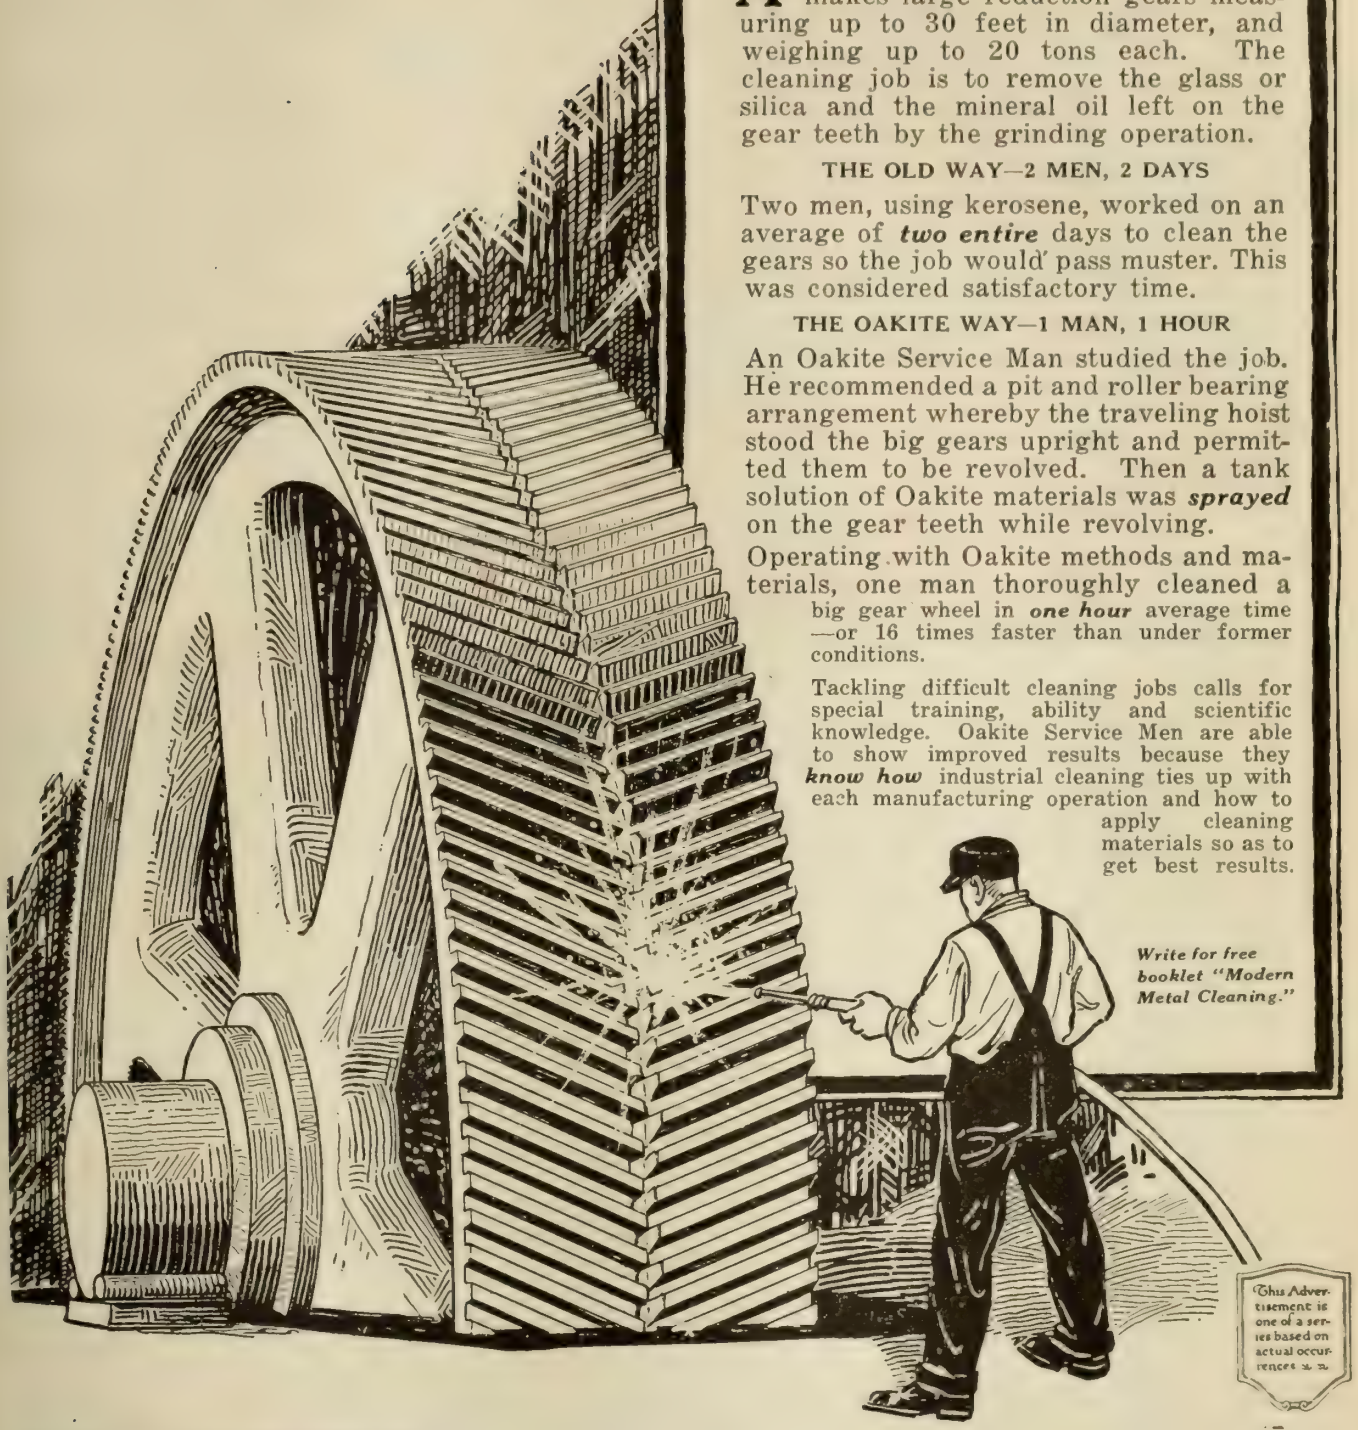
Getting The Best of a Big Cleaning Job

A CERTAIN gear manufacturing plant makes large reduction gears measuring up to 30 feet in diameter, and weighing up to 20 tons each. The cleaning job is to remove the glass or silica and the mineral oil left on the gear teeth by the grinding operation.

THE OLD WAY—2 MEN, 2 DAYS

Two men, using kerosene, worked on an average of ***two entire*** days to clean the gears so the job would pass muster. This was considered satisfactory time.



THE OAKITE WAY—1 MAN, 1 HOUR

An Oakite Service Man studied the job. He recommended a pit and roller bearing arrangement whereby the traveling hoist stood the big gears upright and permitted them to be revolved. Then a tank solution of Oakite materials was ***sprayed*** on the gear teeth while revolving.

Operating with Oakite methods and materials, one man thoroughly cleaned a big gear wheel in ***one hour*** average time —or 16 times faster than under former conditions.

Tackling difficult cleaning jobs calls for special training, ability and scientific knowledge. Oakite Service Men are able to show improved results because they ***know how*** industrial cleaning ties up with each manufacturing operation and how to apply cleaning materials so as to get best results.

Write for free booklet "Modern Metal Cleaning."

This Advertisement is one of a series based on actual occurrences

OAKITE MANUFACTURED BY OAKLEY CHEMICAL CO. 44 THAMES STREET · NEW YORK

When the S.M. talks costs with the G.M.

When the wise General Manager asks his Sales Manager for a bigger share of the business, he explains how lessened factory production costs and a smooth working plant reflect themselves in uniform quality and low prices. That leads right up to the question of correct lubrication.

Correct lubrication with Imperial Lubricants is the one sure way of reducing operating expenses. There is a grade of Imperial Lubricants exactly suited to ***every bearing*** and ***every unit*** around industrial plants. All grades of Imperial Lubricants are scientifically tested and are of uniform high quality.

The service and advice of Imperial Lubrication Engineers is always available whenever needed. Write to 56 Church Street, Toronto.

Genuine Oak Tanned Belting

OF ALL the factors that enter into the making of D. K. McLaren's Belting there is one of first importance—the tanning. Money will buy machinery, buy tools, men and raw materials, all, perhaps, of the best. But only experience can buy the right process. Only years of doing, of testing, investigating and proving, can determine how leather should be treated.

Service on the pulley, hard work under adverse conditions, have demonstrated the value of the D. K. McLaren's process of Genuine Oak Tanning.

Genuine Oak Tanning—the long-time process—is the secret of our success, and on any drive and every drive you designate will prove the secret of service to you.

PRATT & WHITNEY

Reamers

With Eccentric Relief

THE cut below shows our patent eccentric relief which is an exclusive Pratt & Whitney feature. Eccentrically relieved Reamers, as made by us, have the distinguishing advantage that they can be sharpened by grinding on the face of each flute, thus retaining a true working size for a much longer period than is otherwise possible.

Pratt & Whitney Reamers are the only reamers having this eccentric relief, which should not be confused with the so-called "Eccentric tooth," which is nothing more than unequal spacing and adds nothing to the life of the tool.

--a stronger tooth--a smoother hole
--no chatter--maintained size

All P & W Adjustable Reamers have **eccentric** relief, can be set to size without regrinding and can be made to **face the bottom of a hole.**

In order to set these reamers, it is only necessary to loosen the shoes and run back the nuts. The blades can then be pushed back and the shoes tightened slightly. Then, upon coming up with the adjusting nut, the diameter will gradually decrease until the desired size is obtained. Lock-nut and shoes are now firmly tightened and the reamer is ready for use. Quick, positive and convenient.

These reamers are made with 12 different sizes of bodies, giving an adjustment from .020 to .060 in., according to the diameter. Shell, hand or chucking reamers with the same number of body have interchangeable nuts, shoes, screws and wrenches. Shell and chucking reamers with the same number of body have interchangeable blades also.

Effective Cooperation

THE three newspapers you see illustrated here belong to the MacLean Technical Group.

If you are a manufacturer of equipment that can be used in machine shops, metalworking plants, power plants, or foundries, one or all of these papers can give you effective cooperation in increasing sales. Tell the consumer about your products in the columns of these publications. The men who buy industrial equipment read them. Your products may have advantages over other products of their kind. Tell the consumer what they are. Create a desire in his mind to buy your lines when ordering from the dealer.

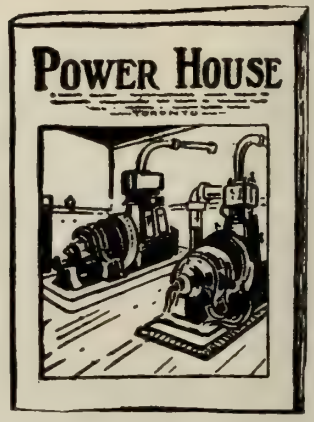
An effective message in MacLean Technical Newspapers will prove effective cooperation for the promotion of sales, and the group you can use to greatest advantage includes:

CANADIAN MACHINERY
AND MANUFACTURING NEWS

POWER HOUSE

CANADIAN FOUNDRYMAN
AND METAL INDUSTRY NEWS

Canadian Machinery serves the iron and steel and general metal working industries.



Power House serves steam, electrical, water and gas power plants.

Canadian Foundryman serves the grey iron, steel and non-ferrous foundries.

Each of these papers covers their respective fields almost exclusively. They are "Canadian National" in scope and are read by the men you are anxious to reach—proprietors, managers, superintendents, purchasing agents and foremen. Attract the attention of these men with a strong appeal in their favorite technical newspaper—the MacLean service staff will assist you.

Standard Dimensions

Something New in Machine Screw Design

For the first time in the history of the Machine Screw business there has been established by us a definite **standard** as to dimension. This new feature makes it "easy" for the user. "Easy" because he is always certain of the correct style and make of taps to insure uniform fits.

If your screw machine operating costs are running high, get in touch with us. A great many parts can be produced by our process at a substantial saving.

A few of our parts are shown at the right. We make a high quality, long-established line of standard and special machine screws, rivets, threaded wires and specialties in headed work.

THE NATIONAL ACME COMPANY

MONTREAL, P.Q.

Link-Belt Silent Chain Drive operating lineshaft Flexible as a Belt Positive as a Gear—More efficient than either.

ALTHOUGH great care is usually exercised in the purchase of machines, small consideration is generally given to the selection and design of the transmission.

In spite of the extremely high relative importance of the transmission and its great influence upon both cost of production and quality of product, it is often selected at random from one of the old forms of transmission, such as gears, belts and pulleys, etc., without consideration of the possibility of vastly superior results that could be obtained from the most suitable drive for the particular service.

Unfortunately, losses from such a source seldom show themselves directly to the management of a concern. Wherever conditions are such that the results produced by the transmission are recorded or noticed, Link-Belt Silent Chain will replace the older and more familiar drive in a large majority of cases.

If you desire to improve the character of work turned out by your machines or if you want to increase their output, give consideration to Link-Belt Silent Chain as the means of transmitting the power.

DOMINION OXYGEN CYLINDERS

LIGHT IN WEIGHT, SAVE FREIGHT

A real money-saving opportunity is offered to you in Dominion Oxygen Service.

For instance, the cylinder while of ample strength to withstand the use and abuse of much handling and transportation, is exceptionally light in weight, which greatly reduces freight and handling charges. The capacity is sufficient to make constant reordering unnecessary.

The green-colored cylinder adopted by Dominion Oxygen is a familiar sight wherever oxygen is used. It is the symbol of oxygen service that represents an outstanding success in the industrial field.

Uniform purity, a system of reliable immediate deliveries, a conveniently handled cylinder of large gas capacity and a liberal policy of cylinder loans make Dominion Oxygen and Dominion Oxygen Service the choice of oxygen users.

Be certain to obtain our price before placing your oxygen order. Order a sample cylinder —it will go forward the day your order is received.

No More Broken Taps *with the* "PROCUNIER" Safety Tapping Attachment

THIS feature is made possible by a balanced reversing mechanism, an exclusive "PROCUNIER" invention. Broken taps become a thing of the past when you adopt the "PROCUNIER" Safety Tapping Attachment.

"PROCUNIER" means speed! Backing out is a necessary time-consuming operation, but the "PROCUNIER" cuts this time in half by reversing at twice the forward speed.

You can secure greater production by adopting "PROCUNIER" Tapping Attachments, Safety Tapping Chucks and Tap Holders.

May we have the opportunity of presenting the full details about "PROCUNIER" economy? Write for full information.

The above is an actual photograph of a man that tapped regularly 1,200 control rod clevises per day, using a 5/16" x 18 tap going ⅞" deep.

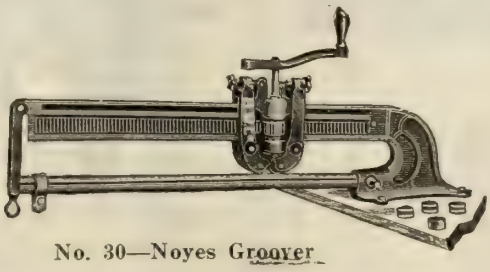
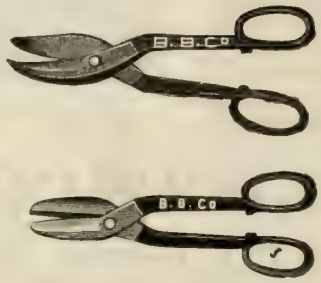
Putting Your Shoulder to--What?



The man who first said: "For greater prosperity everyone must put his shoulder to the wheel," certainly had the needed solution.

There is only one objection so far as we can see. That lies in the kind of wheel used; for pushing against the wrong wheel is wasted energy, pure and simple. Prosperity then depends equally as much on the machine as on the workman.



In the Sheet and Metal Working Field the "B-B" trade-mark guarantees you long dependable service. It is stamped on the machinery listed below.

CONDENSITE CELORON NOISELESS GEARS

"Make Good"

Condensite Celoron marks a new era in silent gears. It is high in dielectric strength and to all practical purposes chemically inert. It is practically water, oil and grease proof. Ordinary solvents such as alcohol, acetone, benzine, etc., do not affect it. It will not absorb the atmosphere nor deteriorate with age. It is highly resilient and amply able to withstand shocks and jars. **Condensite Celoron is self-supporting.** Gears and pinions cut to standard sizes require no shrouds or end plates and can be used under conditions where the use of the average non-metallic gear would be prohibitive.

Gears or pinions cut to specifications or, if desired, we supply the material in blanks cut to specific diameter. Supplied in standard sheets 36″ x 36″ and 36″ x 40″ and standard thickness from 1/32″ to 3″ inclusive.

"The PHOTOSTAT Put These People On Our Books"

"UP to six months ago we were never able to 'land' any of Judson Company's contracts, because we couldn't make the deliveries they asked for. Then I happened to read Floyd W. Parson's article in the Saturday Evening Post called 'The Labor Savers' in which he described the PHOTOSTAT. This machine makes photographic facsimiles directly on sensitized paper of drawings, pencil sketches, blue prints, small machine parts, reports, shipping lists, contracts, catalog pages, maps, production charts, telegrams, advertising layouts and business papers of all kinds.

"We installed a PHOTOSTAT and since that time have been able to get our work into the shop days, and in some cases even weeks, earlier than we used to. The next time we quoted the Judson people we were able to meet their delivery requirements and we landed the contract.

"The PHOTOSTAT makes in a few minutes without error as many copies as we need of the work subjects furnished us, whether they are tracings, pencil sketches or blueprints.

"The PHOTOSTAT has not only made thousands of dollars for us by helping to get new customers; but has also saved us a great deal of time, money and worry in the office. It relieves the stenographers of a lot of copy-work; does it in far less time and NEVER MAKES A MISTAKE. It also saves our advertising man much time in making layouts. And we use it to reduce drawings to convenient size for filing and to copy important documents when we don't want the originals to leave our files. You know PHOTOSTAT copies are legal evidence in court."

In our booklet, "A Good Word for the PHOTOSTAT" many users in widely different industries tell their own experiences with the PHOTOSTAT. Just ask for it.

COLUMBIA

THE BRUSH IT NEEDS!

WHICH is the most suitable brush for any machine depends on correct analysis of all the relevant facts. That is why the Columbia Data Sheet Service improves motor and generator efficiencies.

The essential facts are ascertained by Columbia Brush Specialists. These facts are carefully analyzed by the Columbia Board of Engineers. The Columbia Pyramid Brushes specified as correct for each unit are guaranteed to give satisfactory service.

Columbia Data Sheet Service is at your command. It does not matter whether you have one brush equipped unit or a thousand. Avail yourself of it.

If You Want HOLES,

Straight HOLES and the last HOLE to be as Accurate as the first use "MORSE" DRILLS

Morse Twist Drill & Machine Co.
New Bedford, Mass., U.S.A.

—and when the cutter was taken from the furnace he found—

That its cutting edges were hard and clean—no scale—and could not be ground. It meant much to have their edges clean and true to shape.

That's the kind of results you can get with Hoskins Electric Furnaces. The heat is clean and the temperature control is right under your thumb. The man who does the heat treating does not have to fuss around trying to get the right temperature—he takes care of the **tools,** and **not** the **furnace.** He gets greater production and better tools.

Hoskins Electric Furnace will save you money. Not just for tool rooms are they an economy but wherever metal is heat-treated.

Tell us the work you want done and ask for catalogue No. 122.

CUT GEAR COSTS
WITH THE
New Production Gear Shaper

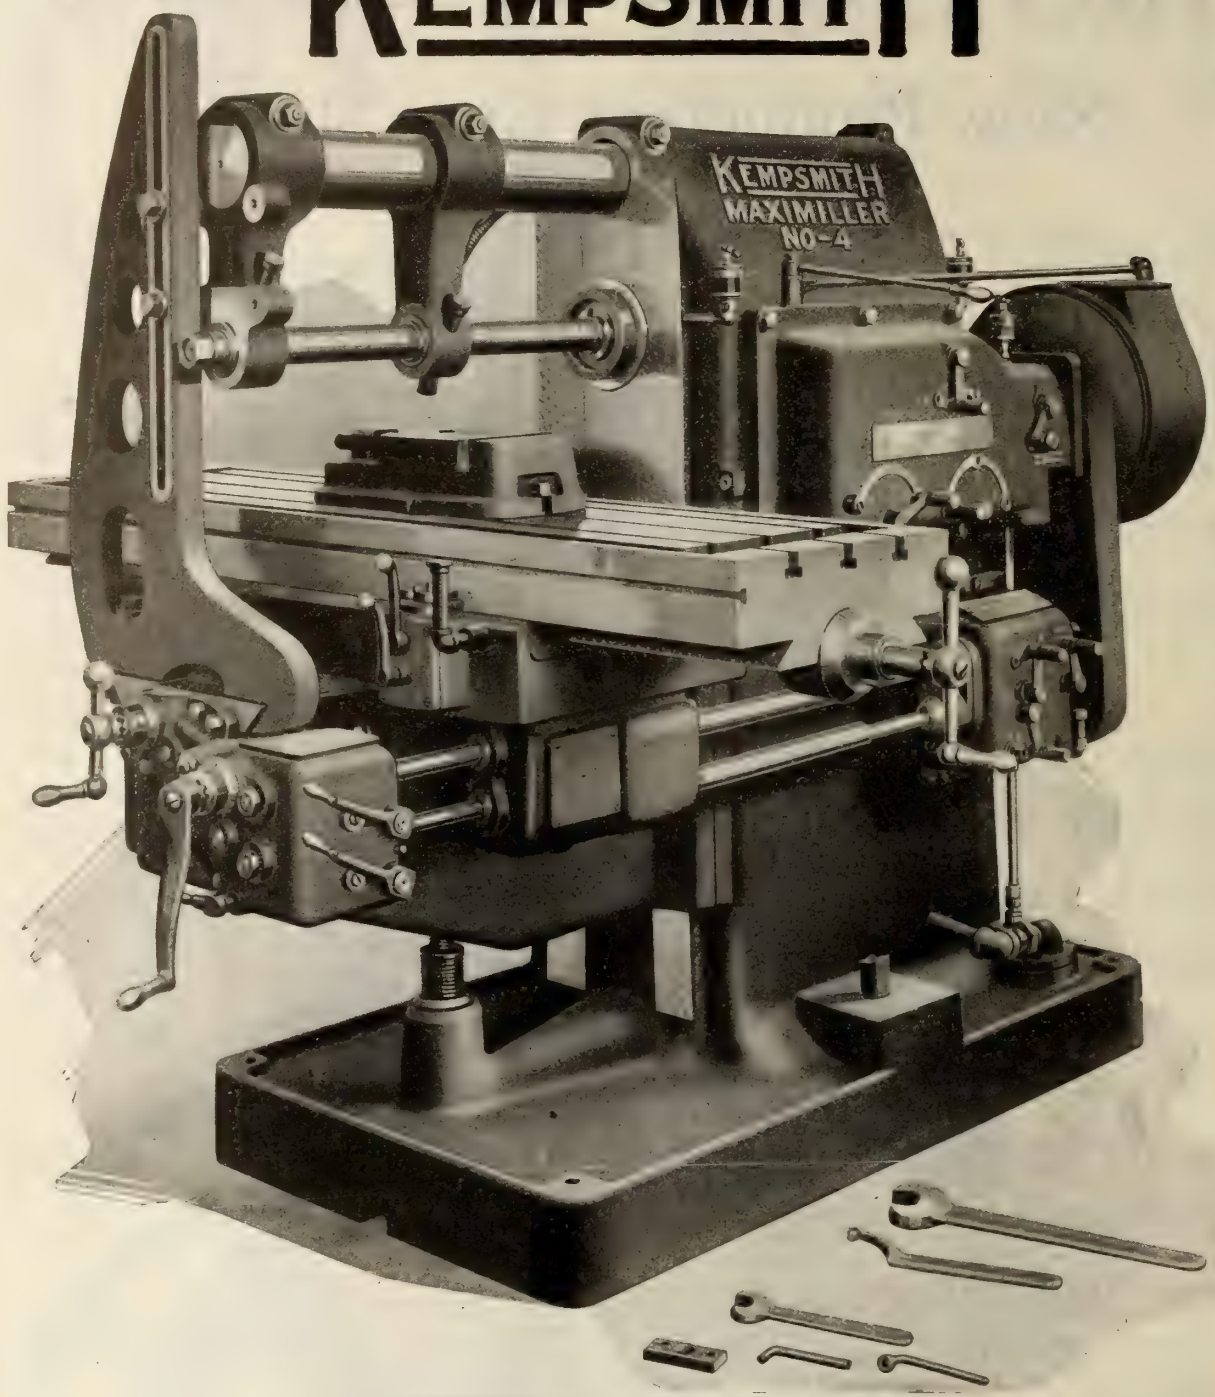
The new production Gear Shaper, illustrated, has been designed to cut gear costs. It incorporates every feature necessary in a gear cutting machine to obtain this result, and still one of the outstanding features of the Gear Shaper principle—accuracy—has been maintained.

It is designed to cut one gear at a time and at a speed which eclipses all other methods.

All operating levers are at the front of the machine, permitting a number to be bolted together and operated as a unit, one 6 H.P. motor furnishing ample power for **10 machines.**

It incorporates to the fullest extent the three principal requirements of production—high speed, accuracy and simplicity of operation.

See illustrated article in all technical **magazines.**



Send for our booklet, "A New Development in Gear Cutting," which has been prepared for the benefit of Engineers and Production Managers interested in the best gear cutting equipment available.

Write for your copy now.

LANDIS THREADING MACHINES

The Choice for Threading Rods Where Both Accuracy and Speed are Essential

Rods! Little rods, big rods, short rods, long rods; auto rods of all descriptions are quickly and accurately threaded on Landis Threading Machines in the Detroit Plant of the F. L. Jacobs Company.

You would be astonished at the number of rods in a modern automobile which are threaded on each end and fitted with drop-forged yokes or eyes.

Material is low-carbon steel, the diameters of which run from 3/16 in. to ½ in. Threads must be straight, and are usually cut .001 in. to .003 in. under standard diameters.

Landis Threading Machines and Landis Die Heads have speeded production, bettered quality and lowered costs in a host of industries. May we show you what Landis equipment will do for you?

Landis Machine Company, Inc.

Waynesboro, Pa., U.S.A.

LANDIS

Improved Grinding!

by the aid of Desmond-Stephan

Diamo-Carbo Dressers

At small cost they keep the wheels dressed and trued. Greatly increase grinding results. They take the place of a Diamond on many jobs such as rough grinding precision wheels, hand forming special shapes, etc.

Diamo-Carbo Dressers consist of a steel tube entirely filled with an intensely hard abrasive. They are stocked in four diameters. Easy and simple to use.

There is a Desmond-Stephan Dresser for every job. Ask for our catalogue.

BLISS SPINNING LATHES

Bliss Spinning Lathe in production

These lathes, built in a number of sizes, are for spinning, burnishing, trimming and wiring the work produced in drawing presses. They are built in the most substantial and careful manner, with hammered steel spindles; the smaller sizes have bronze metal bushings in the head stock and the larger sizes have roller end thrust bearings and Timken roller bearings for spindles in the head stock. Compound slide rests are substantial. They are supplied either right or left handed, and for either inside or outside spinning. Iron cones are furnished. The hardened steel burnishing roll is provided with anti-friction bearings to prevent heating. By use of the tilting rest, all but the largest articles can be spun, trimmed and wired at one setting.

We build special lathes for individual requirements.

Canada's Dependable Machinery and Supply House

This picture shows part of a "Little Giant" Screw Plate; notice the care with which it is put up in its handsome hardwood case; look at the compact and serviceable tap wrench.

YOUR SCREW PLATE SHOULD BE A "LITTLE GIANT"

Sectional View of "Little Giant" Die.

First:

Because **"Little Giant"** Dies can do more work for you than any other.

1. They have a wide range of adjustment. This is money to you if you have to work on both exact and oversize stock.
2. They are reversible in the collet, so you can cut close to a shoulder or other surface, or through the guide on straight work.
3. They can be easily removed from the collet, yet when assembled are as rigid as a solid die.
4. They can be easily resharpened—this means **long** life.

Second:

When parts are lost or worn out they can be quickly replaced at practically every jobbing house in Canada.

Isn't this service worth something to you? Buy from your jobber—if he hasn't **"Little Giant"** Screw Plates in stock, write us.

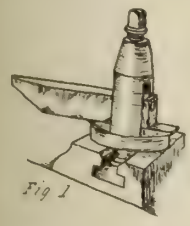
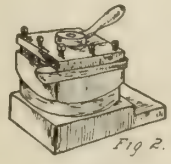
VOL. XXVII, No. 14 APRIL 6, 1922



Keeping the Lathe in a Serviceable Condition



Lathe Still Holds Premier Position—Most Suitable Tool for Small Shop But Must be Kept in Accurate Alignment—Conditions That Develop Spring and Wind—Testing for Accuracy

By H. ALTON

THE progress of industry has given us a wide range of machine tool equipment, both in the improvement of standard designs and the development of special machinery for specific requirements, but the engine lathe still retains the premier position as the most suitable tool for the small shop carrying on a general jobbing business. The small shop that contains a grinding machine is very rare, many small shops are without millers, and many have no shapers or planers but where will you find a machine shop that has not got a lathe?

There are different methods that may be adopted in selecting a lathe. Weight is frequently a factor that influences the purchaser but unless the "weight" is "designed" into the tool, the addition

Fig 1

Fig 2.

metal may not enhance its serviceable qualities. Long wearing of parts, rigidity, appearance, adaptability, and many other qualities are features that require consideration, and not the least point of importance is that the tool should be the product of a manufacturer, whose reputation must be sustained by a high standard of workmanship in every machine placed on the market.

The engine lathe, almost automatically, drops into three classes, namely, the manufacturing lathe, the general utility lathe, and the tool room lathe. As a general rule the small shop wants the utility machine, owing to the wide range of work performed. The relative merits of the solid bed lathes, as opposed to those with fixed or adjustable gaps must be decided only when the conditions under which the tool is to work, are known. Frequently the two-spindle machine is a most serviceable tool.

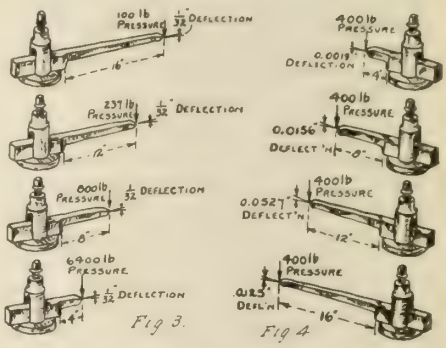
One important point to consider in acquiring a lathe for the jobbing shop is the quick change features of gear and spindle drive. In the large shop, where tools are operating for long periods on one class of work, the quick change is of minor consideration, although even here the saving of time is advantageous. The small shop, however, is often required to make many changes every day and the conservation of time on each change means a great saving in the general total.

One of the weak points in lathe design, and one which is now passing, is the tool post shown in Fig. 1. For light speedy work a post of this nature is very serviceable, but falls down under heavy duty. A design that appears to meet modern requirements is that shown in Fig. 2. This type provides a greater grip for the tool and eliminates slip when taking heavy cuts.

Where quantities of similar pieces are frequently made in the job shop, and where a number of operations are made on each piece it is often advisable to use a removable turret that fits the shears of the lathe. A close study of turret lathe practice will enable the small shop owner to make more effective use of his engine lathes.

Rigidity of Parts

Absence of vibration is probably the most essential requirement in a machine tool, and nowhere is this more noticeable than in the tool holding portions. The effect of the overhang on a lathe tool on the allowable cutting pressure is shown in Fig. 3. Here we see that a pressure of only 100 pounds with a 16 in. overhang, the deflation is



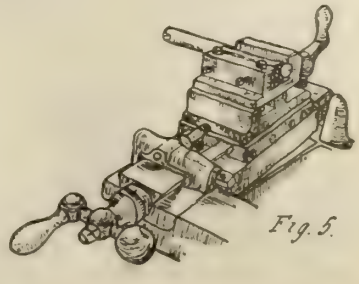


Fig. 1.—Suitable only for light work.
Fig. 2.—For heavy duty operations.
Fig. 3 and 4.—Showing effect of overhang of tool.

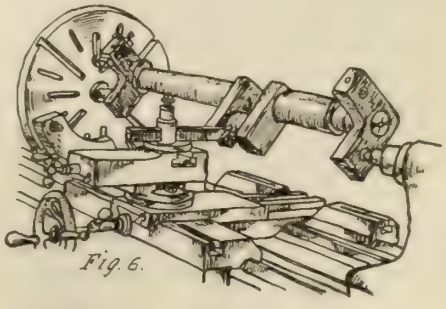
1-32 of an in. Note how rapidly the pressure increases as the overhang is reduced. Again in Fig. 4 note how the deflection of less than .002 in., with a 4 in. overhang and a 400 lb. tool pressure, mutiplies itself under this same tool pressure into a deflection of ⅛ in. to 16 in. Instead of having an assortment of different boring tools of various lengths, it is often cheaper and better to make a holder as shown in Fig. 5.

A good example of rigidity in tool support is shown in Fig. 7, an improvement over the old method shown in Fig. 6. The added holding facilities in the former case enables a much heavier cut to be taken without danger of deflection.

Equal Tool Pressure

Equalizing the tool pressure on work is one way of securing rigidity and ad-

Fig. 5.



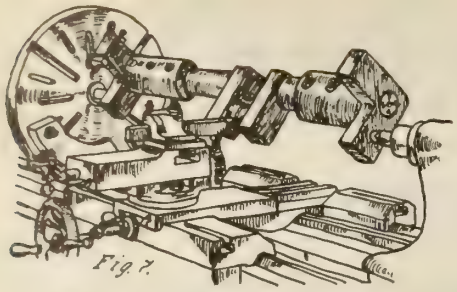


Fig. 6.

Fig. 5.—Effective type of boring tool. Fig. 6.—Inefficient method of turning crank shaft.

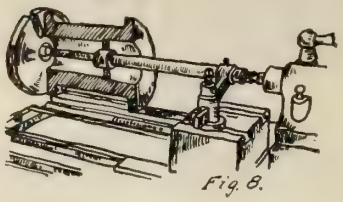

Fig. 7.—Rigid support for tool. Fig. 8.—Special boring bar for long cylinders.

ding to profits. Boring a hole with a cutter head in which the applied force is equalized between two or three evenly spaced cutters is frequently overlooked in the small shop. A simple boring bar is shown in Fig. 8. An arrangement of this kind will assure a true hole on lathes in which the shears are worn out of true, as the alignment depends only on the accuracy of the head and tail centres, and the face plate. Added rigidity is obtained owing to the outer end being supported on the live centre. A set of these bars is a good investment for the small shop.

Lathe Alignment

In order that a lathe may do its best work it is imperative that it be properly installed to maintain the alignment of the different elements. The conditions under which a new lathe is built and tested are, invariably, of an ideal character, and if these conditions are not the same when the tool is placed on the user's floor, the faults developed may be placed against the tool and not on the method of installation, which is nearly always to blame. A lathe is far more sensitive than many mechanics realize, and it would interest those of us who are not familiar with experimental testing practice, to see some of the practical demonstrations in connection with the flexibility of metals.

The writer had the privilege some time ago of observing some of these experiments in the works of Brown and Sharpe at Providence, R. I. The measuring machine used for the purpose is built on the most rigid lines. The frame is between 16 and 18 in. deep at the centre and of exceedingly strong section. The design was made with the idea in view of eliminating spring and distortion, to as great an extent as possible. One thing they do on this machine, is to take an accurately ground plug gauge, and adjust the measuring spindle until this is just held suspended between them. Then they ask you to place your hand under the bed of the machine and lift. As soon as you begin to pull up, the plug drops. The pressure exerted by your hand has been sufficient to spring the bed, and draw apart the measuring spindles.

They repeat this experiment in a somewhat different manner. They place the same plug between the centres, and you are asked to lay your hand on the top of the bed. The expansion of the metal caused by the heat of your hand is sufficient, in a moment or two, to cause the plug to fall. If a rugged machine, such as this is, built particularly for the purpose of withstanding deflection, is subject to such delicate stresses, what can we say about the ordinary machine tool bed? What happens in the long bed of the common engine lathe?

Some men are very particular when they purchase a lathe. When they require a lathe they consult all the catalogs, and then draw up a set of specifications calling for accuracy of one one-thousandth of an inch in 12 inches when boring and turning. They send out letters asking for quotations, requesting the weight of the machine, the size of the main bearings, length of carriage bearing on the shears, speed and feed ratios, and all such information. Then when a lathe that meets all these severe requirements has been purchased and it reaches the shop, in a good many instances it would be set up on a shaky foundation, often on a wooden floor. The bed would be carefully lined up and tested, the bed being made to set level by driving wedges under the legs until the desired setting was accomplished. In a month or two the floor would have taken another sag, and the lathe bed would accommodate itself to the new conditions. Next thing that happened would be a report from one of the men that the lathe would not turn true, or else that it was boring bellmouth holes. Then there would be trouble for the firm that sold the tool. Such men have difficulty in realizing that it takes common sense and judgment to maintain accurate alignment in a tool after it has been purchased, and no matter how carefully the tool has been built, if care is not taken, its accuracy will soon disappear.

The simplest way to test a lathe is to bore and turn with it, but the fact that such a test is unsatisfactory does not prove that the lathe itself is to blame. When you consider the ease with which a lathe bed may be sprung you will realize the truth of this fact. To repeat the experiment made on the measuring machine on a small scale, take any 16 in. or 18 in. lathe and put a bar between the centres and test dial indicator in the tool post. Bring the test indicator to register against the bar. Then put your hand on the under side of the bed and lift. Note what happens to the indicator reading. After this test one will not be so hasty in making complaints about a lathe not in turning or boring true. A little investigation as to where the trouble is, will suggest itself. The modern method of supplying most tools with concrete foundations, is about the best and only method of keeping machines so that accurate work will be turned out over a considerable period. If other foundations are used it is only fair to the machine and the manufacturer, to test a tool frequently to ascertain whether or not an uncertain setting has caused sag or deflection in the bed.

Wind in the Bed

A very important test is one that determines whether or not the lathe bed is free from wind and is level. The way to do this, is shown in Fig. 1. Accurate straight edges and a sensitive level are the appliances used. The bed is first tested for wind, as shown at A, repeating every two and a half or three feet, throughout the length of the bed. Then it is tested for level longitudinally, as shown at D. If a lathe is properly lined up with wedges and then grouted in on a substantial foundation of concrete, it will maintain its level position for a long while. On the other hand if it is placed on a wooden floor, and particularly an upper floor, the wedges must be frequently adjusted. In setting up a lathe that has legs of the cabinet type, always wedge up on the inside of each cabinet leg first, before driving the wedges on the outside edges.

Testing Centre Bearing

The alignment of the centre bearing must be true with the lathe spindle, if the lathe is to do accurate work, on its

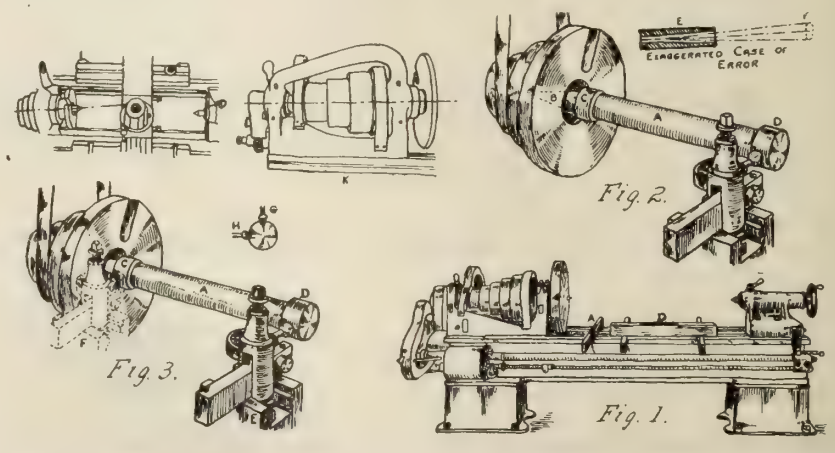

Fig. 1.—Testing for wind and sag in bed. Fig. 2 and 3—Testing alignment of spindle with lathe shears.

centres. This is tested as shown in Fig. 2. First make a test bar A, on an accurate lathe or grinder, this bar having a shank B to fit the head centre bearing. Collars C and D, which are from 12 to 15 inches apart, should be turned to the same diameter. Before putting this bar in the lathe that is to be inspected, it should be carefully tested itself on accurately ground centres with an indicator to see if it runs true at B, C, and D. If found true wipe out the centre bearing carefully and insert the test bar, leaving its outer end D unsupported. Turn the lathe over by hand and indicate the collar D which should run true. If it does not, it is evident that the centre bearing is not true with the lathe spindle, and the amount that it is out in the length of the test bar can be figured from the indicator reading.

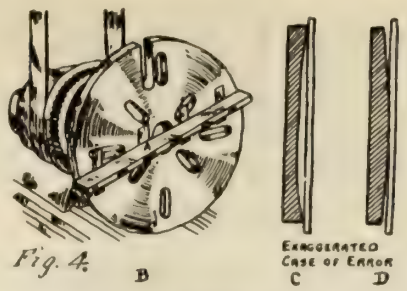
Alignment of Spindle

Another important test is that for alignment of the spindle with the shears, both horizontally and vertically. This is shown in Fig. 3. To make this test, the same bar A is used. The indicator is set on the collar D in the horizontal plane, as shown. The carriage is then moved from E to F in order to get a reading on the collar C. There should be no difference in the readings on the two collars, which, of course, are exactly the same size. If the test is repeated in the vertical plane, as shown at G, it will show whether the centre line is true in this position. A scriber may be used instead of a gauge for both first and second lathe tests if no indicator is at hand, but these tools are so cheap and so generally useful that few shops can afford to be without them.

Alignment of Cross Slide

The alignment of the carriage cross slide is tested as is shown in Fig. 4. A very light cut is taken across the faceplate, and this is tested with an accurate straight-edge A, using tissue paper strips, as shown at B. At C and D are shown exaggerated cases of error. If the faceplate is at all convex the carriage cross shears must be scraped. If it is slightly concave there is no great harm done, as hollow work will bear on its outer edge slightly, which is much better than having the high spot in the centre so that the piece rocks.

The central position of the tail centre, and the alignment of the tail stock



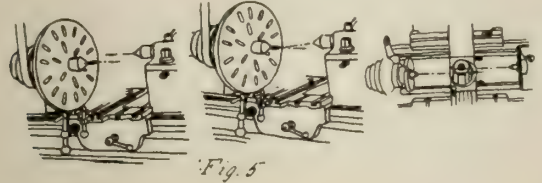


Fig. 4.—Testing alignment of carriage cross slide.

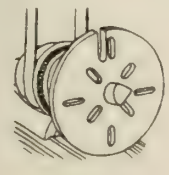
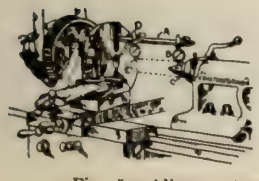


spindle, are checked up as shown in Fig. 5. An angle piece A is selected, which is known to be true. It is strapped to the face-plate, and to this is attached the test indicator B, placed to as to bear against the tail centre, after which the head is rotated by hand, and the gauge B is read on all four quarters. This test gives merely the central position of the tail-stock and does not tell how the tail spindle travels. To check up this point the indicator B is moved to the position shown at D, and the tail centre spindle is advanced to its extreme travel, and the test repeated at E. This will also show whether the head-spindle, although parallel with the shears, has worn low or not. All spindles will wear low in time, particularly if heavy chucking work is done. Lathe spindles are usually set from one to two one-thousandths high, by the manufacturers with this in view, and until they get from one to two one-thousandths low, it is not necessary to put shims under the head-stock or to adjust the bearing boxes.



Testing the Centre Point

All of these other tests may prove satisfactory, and yet the lathe refuse to do accurate turning on centre work. In this case it is due, very likely, to the fact that the live centre is not truly ground. This is tested as is shown in Fig. 6. A bar is placed between centres, and a spot is turned as shown at A, as near as possible to the driving dog. The bar is then reversed and with the spot near the tail centre, it is indicated as shown at B. If this spot runs true, this shows that the head centre is ground accurately.

When it comes down to the last analysis the lathe is simply a machine which is used as a medium for making profits. The speed with which work can be turned out is a very good way to measure the earning capacity of the machine. Probably no one item contributes more to accuracy with high speed, than rigid fixtures. Thus when designing or building lathe tools and fixtures make them rigid. You will find it pays.

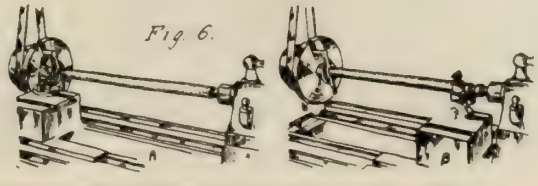


Fig. 5.—Alignment of centres. Fig. 6.—Testing for accuracy of live centre.

STILL IMPROVING THE LOCOMOTIVE

The locomotive, now about a hundred years old, was a British invention; and to-day engineers continue to introduce improvements in its design. Over forty years ago a device known as the "exhaust steam injector" was brought out. Its purpose is to use the power in the exhaust steam from the cylinders to force water into the boiler. The first injector of this kind was able to do its work against a pressure in the boiler of 70 lbs. per square inch. Later it was improved so as to feed at 120 lbs., and for higher pressures it was necessary to call in the aid of live steam from the boiler itself. Lately, however, a British firm invented a modification by means of which the injector can work against a pressure of 150 lbs. per square inch with one pound of exhaust pressure, thus effecting a great economy in live steam. This improvement is due to the use of an additional nozzle which brings the steam into more effective contact with the stream of water. In practice the amount of live steam required when this new device is fitted is nearly half what it was formerly and amounts to only 2½ per cent. of the total steam produced by the boiler.

BUNDLING WOOD BY MACHINERY

Cutting and bundling wood for lighting fires is a process which can be carried out on an economic basis only by very cheap labor or by very simple and efficient machinery. Cheap labor being a rare thing nowadays, there is an increased demand for machinery which will not only chop wood into the required lengths but also arrange the pieces in suitable bundles. A new machine for the latter process was recently constructed by a British firm. The cut wood is fed onto an inclined shoot which delivers them to a conveyor belt running at a considerable speed. It is thrown off the belt on to a slowly moving wheel with partitions into which the pieces fall. Any piece which does not happen to fall into a partition drops back again and is carried once more to the shoot. The partitions deliver into a trough with an opening at the bottom, through which the pieces fall into boxes. As each box is filled, the operator presses a foot plate which removes the full box and brings another into place for filling. The whole process is exceedingly rapid and the machine can be worked by one unskilled operator.

Mr. Morrison, who has been associated for some time with the Baines and David steel merchants, Toronto, is leaving his position to enter the accounting business.

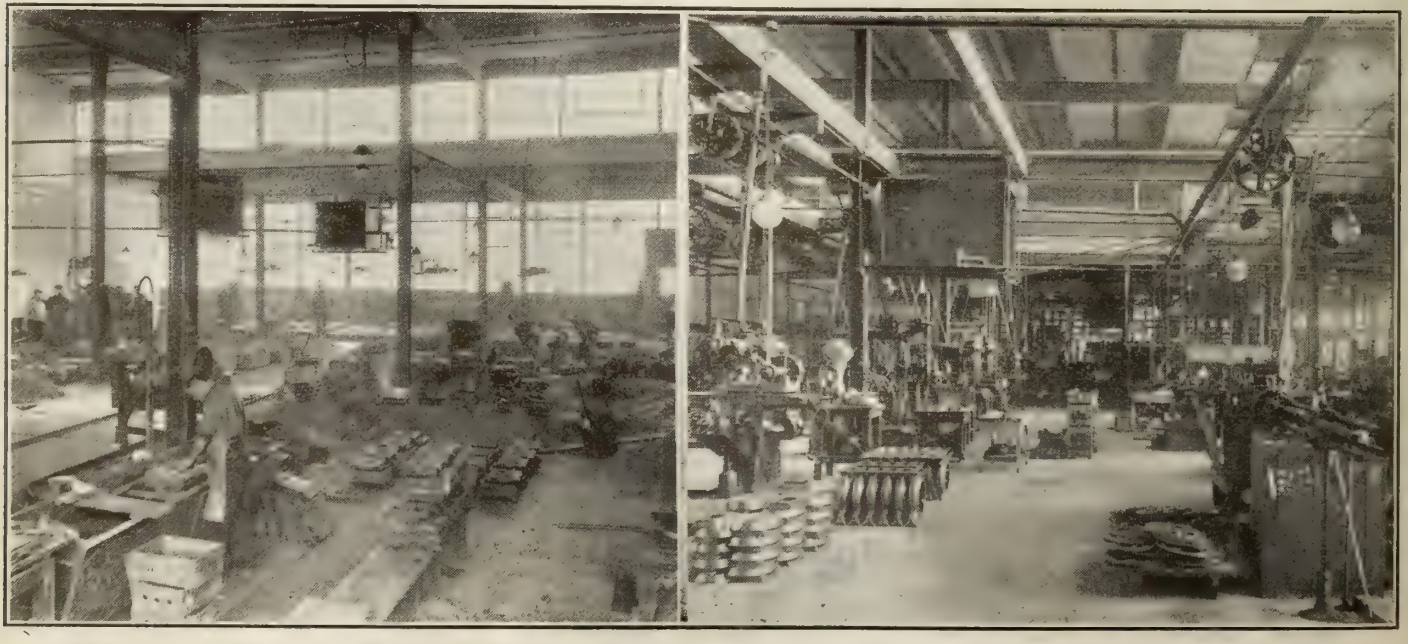
Reducing Operating Costs by Careful Planning

Importance of Proper Routing Has Been Realized by This Plant —Good Lighting is Also a Feature—Jigs and Fixtures Have Reduced Costs and Increased Production

By J. H. MOORE

WHEN MANUFACTURING any product, it is very important that the plant manager arrange his departments in such a manner, that so far as possible, the part, or machine being made, passes through the factory with as little backing up in routing as possible. The importance of proper routing is unquestioned, for it may mean the difference between profit and loss. The wasted time in some plants, which refuse to give routing the consideration it deserves, is amazing. The average factory, however, is beginning to realize the necessity of planning the route of a product, just as one would plan a journey to cover as much ground as possible with the least effort, so that in many cases profits have increased since improvement in routing has taken place.

The logical place to begin planning is when the factory is being built, and the Brantford Computing Scales Co., Brantford, Ontario, had this though in mind when they laid out their present plant. From one end of the factory to the other, everything has been carefully considered, with the result that their product starts in the foundry at one end, and goes out the shipping door at the other. The plant occupies approximately 60,000 sq. ft., and they have about four acres for expansion when required. Two railway sidings are incorporated, with shunting privileges on another line. In this way shipping facilities are provided for.



A feature of the entire plant is its good lighting. There are no dark shadows to contend with, the result being, workmen can turn out an accurate job, such as is required in scale work, without eye strain. Starting from the extreme end, we find the foundry separated from the rest of the factory by a fire wall. The photograph at Fig. 1, speaks for itself, because it shows clearly the light provided, and the neat arrangement of the foundry generally. Cast iron, brass, and aluminum castings are made, and they specialize in light casting work of all kinds, doing outside work as well as castings for their own product. The heaviest piece they make weighs about 80 pounds, and this is the base for their meat slicer. Twenty men are employed in the molding shop, and at present they pour three times a week. The cupola room, which is directly adjoining the foundry, is well laid out, and everything is carefully weighed before entering the cupola. This is very important, as owing to the light nature of castings made, the grade of iron poured must be absolutely correct.

No waste is tolerated throughout the entire plant, and nothing is sold to junk dealers. All scrap, cuttings, etc., go to the storage yard outside the plant, which is also adjacent to the cupola room. An oxy-acetylene outfit is used in the foundry as a means of reclaiming and building up small defects which may occur. The type of outside castings made covers quite a varied field, including, automobile jack castings, parts for washing machines, electric fixture castings, smoking stand parts, book rests, and all sorts of novelties.

Coming from the foundry we enter the mill room where castings are cleaned before going into stock. On leaving the mill room they must pass over a scale before getting to the raw material stock room, and in this way a careful check is kept on the tonnage of castings leaving the foundry. Should raw material, strip steel, or any other material purchased outside come to the factory, it is received at a door opposite the raw material stock room, and it also has to pass over the scale before entering the room, so that a close check on outside material is likewise kept.

Raw Stock Room

In the raw material stock room we find a carefully laid out department with well arranged bins, each having its own card to show the amount of parts in stock. Racks for bar stock, etc., are also provided, each section and size being plainly marked. A feature in this department is the blueprints used to show the parts going into a specified number of scales, or meat slicers, as the case may be. Usually, these are put through in lots of twenty-five, or one hundred, and the stock keeper can immediately tell from his blueprints, what parts he has to issue. A portion of one of these sheets is shown at Fig. 2. Later on, in the finished stock room, the store keeper in that room, checks up the number of parts received from a similar set of blueprints, so that they know exactly if anything has been spoiled between the two departments. In the list,

Figs. 1 and 3.—Foundry and machine shop of the Brantford Computing Scale Co.

a reasonable amount is allowed for wastage, as it is realized no factory can run 100 per cent. efficient. Should further stock be required, the foreman of the particular department needing the extra parts must make out a surplus stock order, and of course this shows him up, and he must account for the discrepancy.

Should any parts require grinding or polishing, before entering the raw material stock room, they go to the polishing room which is almost alongside the stock room. A splendid dust exhaust system is used in this department keeping atmosphere clear, and when castings are weigh'y, swinging cradles are used at t.e machines to support the work.

The Machine Shop

The machine shop, a small portion of which is shown at Fig. 3, is well arranged, wide aisles being the rule, rather than the exception. The machines are laid out on the floor to a predetermined plan, the parts passing from one machine to another with as little waste movement as possible.

Several of the operations are of extreme interest, and in a later article we will show some of the jigs used, but at present will confine this story to the description of the plant itself. Only high-class machine tools are used, as accuracy is essential in the making of their product.

Leading from the machine shop is the tool storage room, where all jigs, drills, cutters, etc., are stored. A double check system is used when issuing tools to the workmen, this holding them directly reponsible. Next to the tool storage, is the tool grinding room, and one man attends to all grinding. Every workman is not allowed to grind tools to his own liking, but an expert attends to this work entirely, this increasing the life and efficiency of the various tools.

Alongside of the latter room, and close to the machine shop, is the part inspection room. Here all parts must pass inspection before going any further, and incidentally, this is the second inspection, as all castings leaving the foundry are inspected before entering the raw material stock room.

Leaving this room, the parts proceed to the first paint room, when they are given a coat of anti-rust and a coat of filler, later being baked in an oven. After this they proceed to the finishing paint room, receiving various numbers of coats, depending upon the nature of finish desired. Air paint brushes are used, except where hand striping is done. An expert in this line makes some remarkable effects by hand, and handles the transfer work as well. A baking oven is also used in this department.

Where required, pieces leave the part inspection room and go to the electro-plating room, where the necessary finish is arranged for. Special holding racks are used in order to prevent the operator marring the finished surface.

After the parts leave either the paint room, or the electro-plating department, as the case may be, they pass into the finished stock room where they are arranged and carefully handled, as some of the castings have a very high glossed surface.

Assembly Room

We now come to the assembly room, this being arranged in two sections, one for scales, the other for slicers and cheese cutters. A foreman is in charge of each section, and gets his parts from the finished stock room which is very handy to both departments. Fig 4 shows a small portion of the scale assembly room, and the product is arranged on long tables as shown, gradually working up to a finished article. After the scale is properly balanced, a government inspector checks it up, seals the balance chamber, and puts his O. K. on the finished product.

A large variety of styles are made covering the grocery, meat, hardware, candy, and other trades, cylinder and dial types being generally used. Specially arranged dials compute the amount to be charged, depending upon the price per pound, as well as the weight. After the scales are inspected, they go to the shipping room, where they are packed, and here again the value of careful planning is noted, for the style of boxes best suited to the various types of scales, etc., has been carefully studied. Passing from the shipping room, they go direct to the cars, in this way having had a continuous journey from one end of the plant to the other.

The general offices, drafting room, etc., are situated at the extreme end of building away from the foundry, and here we also find that the various separate offices have been arranged with a view to efficiency.

Purposely, we have left out mention of the tool room until the present time, as it is outside of the regular manufacturing process. Directly next to the tool storage room, and tool grinding room, is the tool room where all jigs, fixtures, etc., are made. Cribs lead into both of the former mentioned departments, so that close communication with each other is always possible. The class of work being performed in the tool room is of a very high order as will be seen when we publish the later article dealing with the jigs used when making various parts of the scale and meat slicer.

The system of heating and ventilating the plant is worthy of notice. In both Fig. 1 and Fig. 3, sheet metal boxes can be seen suspended from the beams. These are units in heat system known as the Vento Unit, and briefly,

Successful Collection of Overdue Accounts

Making the Debtor Realize His Obligations—Handling the Slow Payer, the Careless Debtor and the Indifferent Type—Each Must be Dealt With in Different Manner—Sample Letters

By M. L. QUIGLEY

PROCURING prompt settlement of accounts is a problem which confronts practically every business house today. It does not make any difference what the nature of the business so long as credit is granted. It seems to be a natural consequence to have a number of slow acounts.

Nearly every business is carried on on a credit basis, and until such time as some means can be devised to put all business transactions on a strictly "cash with order basis," this condition of affairs will prevail. While it is impossible, under existing conditions, to to each individual, in order to get the accounts, we can, by judicious and systematic handling, prevent a great many losses.

Practically every business man realizes that to some degree, his success or failure depends on his credit standing, and whether or not he may get behind with his obligations. He realizes that this standing is his chief asset, and by reminding him courteously and firmly of this fact it will be the means of spurring him on to greater effort to adjust his accounts, and this line of appeal can be made with good effect on most any debtor.

All debtors, of course, are not slow or indifferent in their payments from the same cause, but if there is any sense of responsibility at all, a man will endeavor to preserve as far as possible, the credit standing he feels he should enjoy, and when he sees visions of losing this, it is wonderful the efforts he will put forth to retain it. Not including the debtor who pays promptly, and with whom there is never any trouble or delay, we might place the rest in four classes, slow, careless, indifferent and unscrupulous. There are many reasons which probably tend to make a debtor slow, and all slow debtors cannot be placed in the same category.

Methods of Handling Vary

Some people have a slow way of doing everything, and even payment of their accounts is undertaken in the same way. A debtor may be perfectly good in every way, but month after month, he is content to let his bills go past maturity, and be written to and dunned repeatedly before he makes settlement. These debtors cannot all be handled in the same way, so that to get the best results every case should be handled on its own merits. While an appeal to a certain motive in one man might get results, it would have no effect whatever, with another.

Through long handling of such accounts, you become accustomed to the nature and disposition of each debtor and are in a position to know what particular kind of appeal should be made to each individual, in order to get the best results.

The Careless Type

Particular attention should be paid to the careless debtor, because if he is permitted to continue in his own way of doing business he will, in all probability, go from bad to worse, but if influence can be brought to bear upon him in such a way as to make him sit down and realize his responsibility and put before him in a friendly way the results of his carelessness in handling his business, he will probably realize that you have, aside from the account altogether, a friendly interest in him, and will make an effort to justify the confidence which he believes you still have in him by making a determined effort to do better. Once this desire is aroused to do business in a business-like way, you have started him along the right way, and by reminding him regularly of his duty, it will only be a question of time until he will acquire the habit of paying promptly. This habit, like all habits, will be more pronounced as time goes on.

We are all human, and no matter how careless we are, we appreciate kindness or assistance, and there is a natural inborn desire to show appreciation for confidence which may be placed in us.

The Indifferent Type

Indifference is the reason for a great many debtors getting behind in their obligations, and a special appeal to this class of debtor to his sense of honesty will, as a rule, bring good results. Whether a man is sincere or honest at heart or not, he likes to leave the impression that he is, and by appealing to him, and assuming you have confidence in him, as a general rule his pride will assert itself and spur him on to action in order to justify himself with you. Persistent and strong appeals with an occasional telegram sent to this class

Dear Sir:—

We did not anticipate, when we wrote you a short time ago that it would again be necessary to remind you of your account which is still unpaid. We felt after the different appeals made to you that you would fully appreciate the importance of having this payment made and that it would have received attention before this.

While we are always anxious, and endeavor to oblige our customers in any way we can, sometimes at considerable inconvenience to ourselves, we feel, when a special appeal is made for payment as has been made in your case, that we ought to be shown the same consideration. You have, however, simply ignored the different appeals made to you although we would suppose if there was any just reason for the account being delayed this long, you would be most anxious to advise us of it, and not leave the impression by the indifference which you have shown, that payment was being purposely withheld.

If you looked at this in the proper light you would realise that there is more involved in this matter than simply payment of an account as if we are obliged to resort to some other method of collection, it will reflect greatly on the credit standing which you now enjoy and as the success of your business depends to a great extent upon the confidence of the people with whom you are doing business, we would naturally suppose that you would be very careful to prevent anything happening which would in any way jeopardize this confidence.

We trust you realise that the adjustment of this account means considerably more than simply the payment of dollars and cents and that you will put matters right by sending immediate settlement.

Yours truly,

Author is manager of collection department at The Ontario Wind Engine and Pump Co., Toronto.

Dear Sir:—

After the length of time we have already allowed on your past due account of $85.00, we naturally felt, when the draft recently made upon you was presented for payment, that it would have received consideration, but you have allowed it to be returned without any attention, in fact the bank advises that no response was made to the notice sent you.

To say the least, we think this is very unfair treatment when you consider the way you have been used in connection with this account as we have carried it at considerable inconvenience to ourselves and have not unduly pressed you up to the present time for payment. Common courtesy would demand at least a reply to our letters, or some reason for the draft being returned, but you have given neither although we would suppose that you would be most anxious to correct any false impressions which might be made owing to this draft being returned unpaid.

Please understand that this account cannot be carried for further time and it will be to your best interests to have remittance made immediately on receipt of this letter.

Yours truly,

of debtor will generally bring him to the sense of his responsibility, as once his affairs are made somewhat public, as they are having telegrams forwarded, he will be very desirous to prevent any false impressions being broadcast, and will, in all probability, attend to his obligations at once.

As a rule, ordinary collection letters to the unscrupulous debtor will be of little avail as such a man has become so hardened to this kind of thing. He has been through the mill so often that ordinary appeals have little or no effect. This class is naturally condemned and abused to a certain degree by all he has done business with, and receives as a rule, practically the same treatment from all he may be owing.

It sometimes happens, that if instead of threatening and appealing along the usual line, a special appeal is made, making it quite plain that you understand the position he is in and what others are doing in regards to collection of their accounts, it may have the effect of bringing results which you never expected, for being used to receiving scathing letters and threats, a different kind of appeal may strike the one good quality in him, and as this is only a chance anyway with the collection of an account of this nature, it does no harm to try the idea out.

The best way, however, once you find you have given this kind of man credit, is to call upon him immediately and get some reason or explanation for his not paying up. He cannot refuse to answer you or pay any attention to you the same as he would to a letter, and if there is any possibility of getting adjustment at all, your chances are much greater by actually getting in contact with him. Failing this, you still have recourse through the court.

In sending letters, or requesting payment of accounts, there is one fact that perhaps is forgotten or overlooked by the majority of letter writers, and it is this. That you are under no compliment in writing to this debtor for payment of his account, as the account itself is the result of credit given him, and credit in the first place, is really a favor conferred.

Business is a very serious affair and sincerity should stamp every action. Whether in selling goods or writing collection letters, there should be the same strain of sincerity throughout, and to my mind, letters should not be written in a jocular way, particularly to a debtor whom you have never met personally as it is possible that they will convey the opposite impression to what was intended.

The best example of business being done in a business-like way is perhaps shown in the manner in which obligations such as notes are taken care of in the banks. Every man who has a note falling due in the bank is most anxious to take care of it in some way, either by payment or renewal, and this desire is created simply through the system and policy of the bank in insisting on these obligations being taken care of at maturity. This can be created in the same way by making your debtors feel that you look upon settlement of their obligations on time as a serious matter, and by insisting on these being taken care of. If you are careless, your debtors will probably acquire the same habit.

When starting to use a new grinding wheel it should be run at full speed for a minute or two before applying the work, the operator standing clear during this brief period.

REDUCING OPERATING COSTS BY CAREFUL PLANNING

(Continued from Page 37)

here is how the system works. A fan draws in the air from the shop at the rear end of each unit, passes it over heated coils inside the box, and throws it out, over deflectors at the other end, in any desired positions, the result being an evenly heated or ventilated shop at all times. As far as we can learn, this was the first of its kind to be installed in Canada. The Ford Motor Co., Detroit, used it with good success, this fact prompting the firm whose plant is described, to adopt the system.

Referring to Fig. 3, it will be noted that an addition has been made by erecting a top floor over a certain portion of the plant. This new section will be used for light assembly work, and will be provided with a rest room, and all other conveniences. The experimental department will also be situated on this floor.

Outside the main building is the boiler room, heat treating department, and pattern storage. This is a separate unit, and a 115 h.p. boiler is used for heating purposes. In summer, a small auxiliary boiler is sufficient, as only the plating room requires steam at that time. The Dunham drip trap system is used.

In order to reduce the charges for water used in the plant, this firm decided to dig their own well, using the water secured for their plating room. The ground through which the well had to be dug was rather good gravel, so they hired a well digger on the understanding that he would charge so much for every foot he went down until he struck water. Another stipulation was that the firm owned the gravel brought from the hole. This being agreeable to all concerned, the well was made, and the gravel secured was used in the laying of the power house cement floor. When everything was totalled up, it was found that the saving effected in securing the gravel free, paid for the digging of the well.

This story shows how carefully every item is planned, and the thought placed on the well episode, is given in still greater proportion to the process of manufacture. Nothing is done without a good reason, and every department is arranged to be of as much help to the next one as possible. The operations are likewise planned, with the result that waste time is reduced to a minimum. A spirit of co-operation exists through the entire plant, and owing to the policy of the management, and the excellent working conditions provided, they have never experienced any labor trouble. The plant is running at normal, employs about 200, and hopes when conditions warrant, to still further branch out, building a separate foundry, enlarging the present machine shop, and making other important changes.

Increasing Output by Means of Turret Lathe

Actual Cutting Time Reduced by Use of Multiple Tools—Attachments That Aid Rigidity and Increase Production—Taper Turning and Threading

By J. H. RODGERS

FROM the standpoint of quantity production systematic machining of work is an essential factor. The material of which the piece is composed and the nature of the different detail operations will generally determine the class of tool best suited for the purpose. Due consideration, however, must be given to the volume of work, of a certain character, that can be performed on any one particular machine. Where sufficient work is available with-

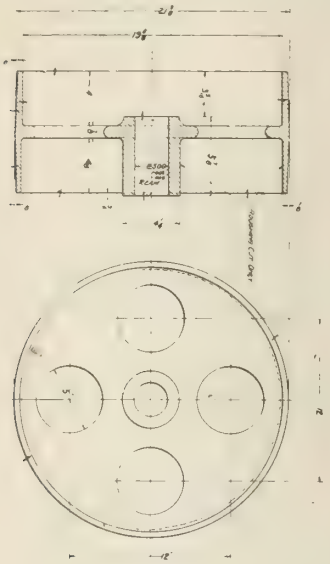

Fig. 4.—Showing dimensions of pulley in Fig. 3.

in the production range of automatic or semi-automatic machines, the installation of such equipment is often an economical investment.

Illustrations obtained through courtesy of International Machine Tool Co., Indianapolis, Ind.

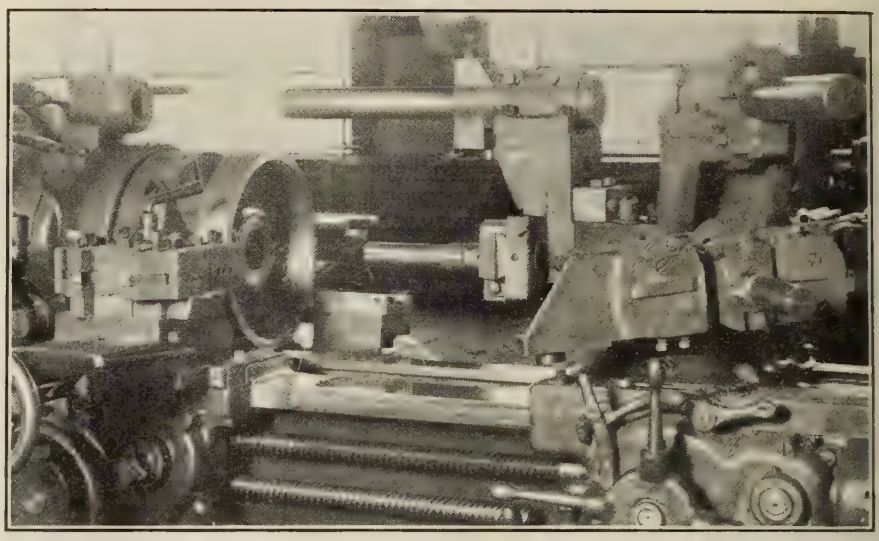

Fig. 2.—Machining cast iron fly wheel on turret lathe.

Manufacturing requirements to-day necessitate the use of heavy duty machinery, where the maximum amount of material must be removed in the minimum space of time. Not only is it a case of removing metal but likewise the conservation of unproductive time in the changing and setting of tools and cutters between the various operations. This latter phase of shop practice is one that has accelerated the development of the automatic type of machine tool.

Multiple Tooling

Turning has, until recent years, been more or less recognized as single tool machine work where no more than one tool was working at the same time. The demands for increased output resulted in machines of more rigid design, and subsequently the multiple tooling system. This last mentioned feature is one that is difficult to incorporate into the ordinary engine lathe, and in consequence the turret machine has, in many instances, replaced the former for production of duplicate parts.

One of the advantages of the turret lathe, where a number of similar parts are to be machined, is the fact that once the cutters are set for the various detail operations the work on all the pieces can be performed without the resetting of the different tools, thus saving valuable time and eliminating the necessity of gauging the work when each operation is commenced. The turret likewise provides an almost unlimited means

of using attachments for machining different surfaces at the one time. In addition to this, the tools in the forward carriage may be working on the piece simultaneously

Machining Special Pulley

The accompanying illustrations shows several pieces of work that have been handled to advantage on Libby lathes. Fig. 1 shows a heavy duty turret lathe

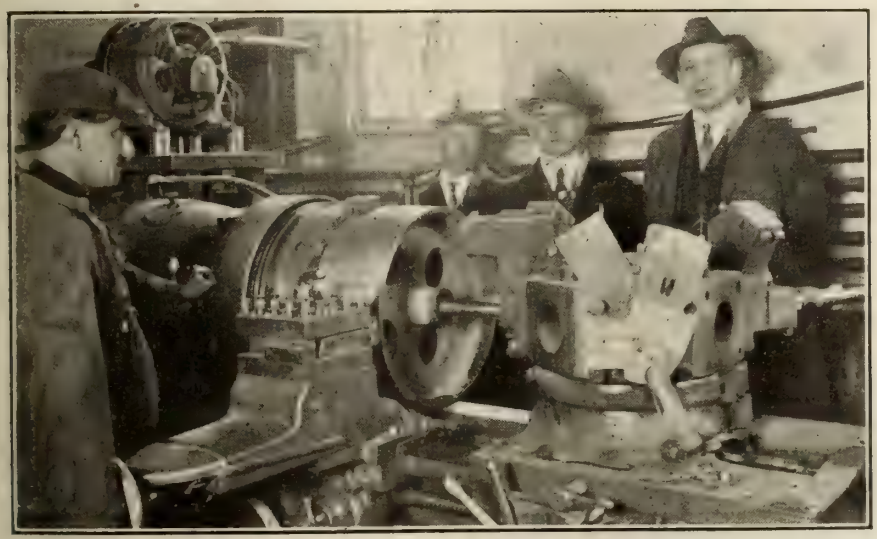

Fig. 3.—Turning, boring and facing large pulley.

machining a ball bearing centrifugal spindle pulley at the plant of the Cresson-Norris Co. of Philadelphia. The piece is 16½ in. dia. and has a hub 15¼ in. long. The boring bars are provided with long pilots which are supported in a bushing in the hollow spindle of the head stock. The space between the hub and the outer shell is machined by a tool secured to the small turret on the forward carriage. Recessing the bore is accomplished by means of boring bar fitted to a movable slide on one of the main turret faces. The collar of the hub is finished with a tool held in a special block that has a vertical adjustment, the work being supported by means of a pilot the full size of the bore. The weight of this piece, finished, is 309 lbs. It is machined all over, as shown, in 2 hrs. and 32 min., a saving of approximately 80 per cent over the previous method.

Automobile Fly Wheel

Fig. 2 shows an 18 in. automobile fly wheel being machined. The piece is turned on the outside diameter, faced on both edges, taper turned on inside for friction clutch, and bored and faced on the front side of hub in the average production time of 9 minutes each. Added rigidity is obtained by means of a special pilot bar that is elevated above the work and is supported, when tools are working, in a bearing located on the front housing of the head stock. The rim is faced and sized by tools in the forward turret.

Fig. 3 illustrates the machining of a 22 in. dia. cast iron pulley. The piece

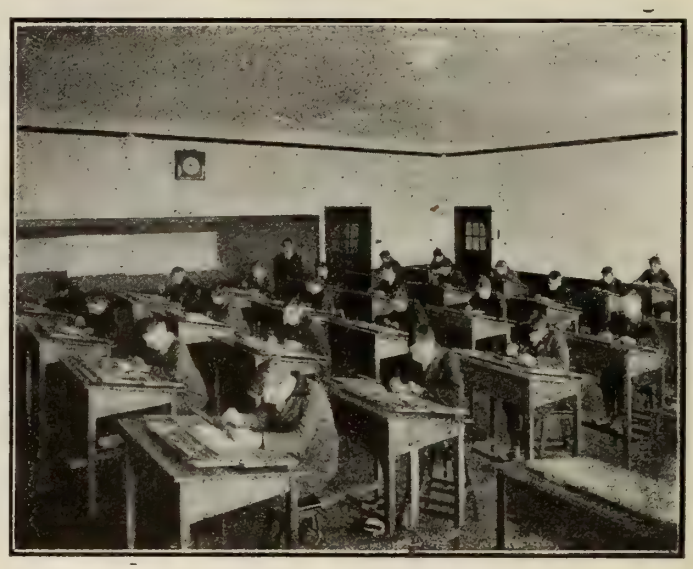
Intelligent Choice Made By School Students



Steady Growth of Attendance—Additions to be Made to Original Building—Students May Specialize After Second Year—Evening Classes Well Attended

By H. B. BEAL
Principal London Technical and Art School

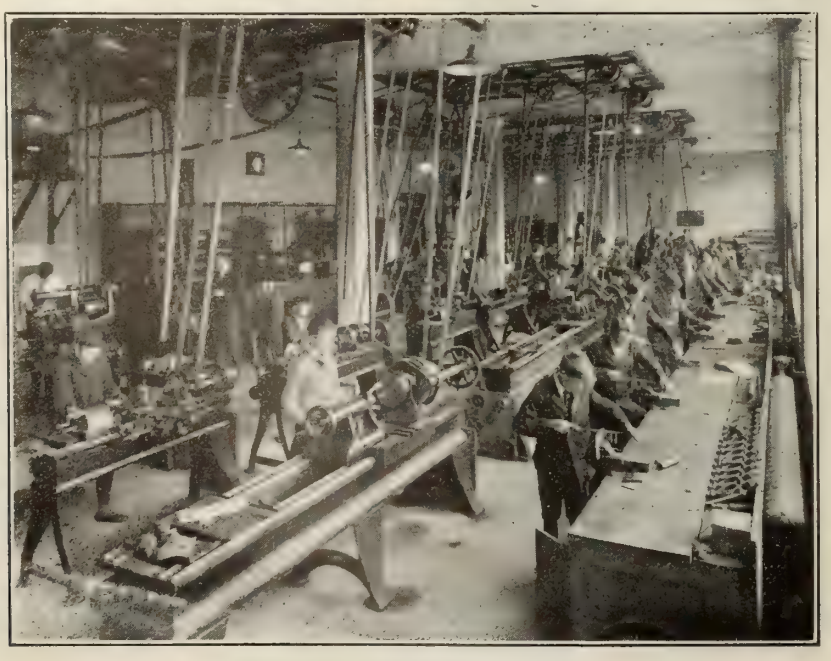
THE LONDON Technical and Art School is one of the pioneer institutions for vocational education in Ontario. From a very humble beginning in 1912 in an old and discarded public school building, it has steadily grown till to-day it is one of the best equipped technical school institutions in Canada. the spacious first unit, which when it was opened in 1918, it was freely predicted would never be filled. The London school board is at the present time receiving tenders for the first addition to the original building.

The readers of this article will be particularly interested in the facilities provided for the training of boys and young men. In addition t othe academic class rooms and science laboratories where mathematics and science as applied to the shop departments are emphasized, the school contains a well-equipped machine shop, woodworking and finishing room with complete power mill machinery and bench equipment for two full classes, an electric wiring room, automobile department, plumbing department and two draughting rooms.

In addition to matriculation courses leading to the engineering and applied science departments of the University there are full time general industrial and technical courses for boys. In these courses boys devote one half of their time during the first two years of their course to academic studies of high school grade, but correlated to the shop work of the school and the other half of school time is devoted to machine shop practice, woodworking, electrical work, draughting, materials and applied science. These two years provide a good general education and a variety of shop work which enables students to make an intelligent choice of a practical course in which to specialize during the third year. The final year, or two years if desired, may then be devoted to specialization in one practical department as a major subject with the draughting, mathematics and science related to it.

View of drafting room at London school

A considerable and increasing number of students who have left school and have been in industrial establishments long enough to find out that they require further training to fit them for success in the industrial world enter the technical school for special full time day courses. More than forty of such students are at present taking machine shop and woodworking training.



Evening classes attract many young men from the local industries. These classes cover a large variety of practical subjects including machine shop practice, welding, plumbing and steam fitting, cabinet making, carpentry, joinery and mill superintendence, roof framing and stair building, stationary engineering, electric wiring, wood carving, science of electricity, machine draughting, architectural draughting, sheet metal draughting, show card writing, art, industrial design, industrial chemistry and mathematics.

For the benefit of students in the automobile classes, the following equipment is available: 1 Hudson-four car; one McLaughlin-four car; one Cadillac-four car; one Oldsmobile-eight car; one Peerless-four car; one Ford car; one Curtiss aeroplane V-type eight cylinder engine; one rotary aeroplane eight cylinder engine; one Peerless eight cylinder engine, working model; one Fairbanks two cylinder 1½ h.p. stationary motor; descriptive charts with blue prints of engines and mechanisms; full equipment of tools.

Woodworking classes are furnished with the following:

1 Cowan 12-in. circular rip and cross-cut saw with hollow chisel mortise attachment; 1 24-in. Cowan thickness plan-

Classes Organized According to Local Needs

Large Registration in Each Class—Courses of a Practical Character—Applicants Given an Intelligence Test—Women Interested in Automotive Instruction—Commercial Courses Well Attended

By G. E. EVANS
Principal Port Hope High School.

FOR a number of years evening courses in technical education have been conducted in Port Hope, the classes meeting in the high school two hours twice a week. Organized work so far include the following subjects:—Mechanical drawing, English, and arithmetic, automobile mechanics, bookkeeping, typewriting and stenography, home nursing and first aid, millinery and dressmaking. This selection of subjects was decided on after a survey of the local requirements and the industrial occupations available for adults in the town and vicinity. The initial registration and steady increase in attendance from the beginning has been very encouraging, and the fact that there has been a large number registered in each class since its inception has amply proven the wisdom of the choice of these subjects.

The class in mechanical drawing has proven attractive to the employees of several local factories where there are regular draughting departments. The aim of the course is to enable those taking it to read and interpret a blueprint. In the short time at the disposal of instructor and student it is, of course, impossible to take up an extended study of the principles and theories involved in this subject, but the instructor brings as much theory into his explanations as is feasible. The aim is that the course shall be practical and that beneficial results shall be achieved each night. Regular drawing instruments and boards are used, and some of the work done by the students in actual draughting is really excellent, to say nothing of the skill attained in reading and interpreting the blueprint.

In English and arithmetic there is an astonishingly large number who apparently have not got beyond the rudiments of the three R's. The demand seems to be for training in reading, writing, spelling, and in the simple arithmetical operations. That this demand for the more elementary phases of these subjects is not necessarily due to any mental deficiency or retardation on the part of the students has been clearly shown by the use of intelligence tests; and the results of educational tests, when applied in the subjects concerned at different times, afford evidence of steady improvement. The Ayres' spelling test, the Thorndyke or Hamilton writing scales, and various silent reading tests have been particularly valuable in the latter regard. These tests are so standardized, and scientifically constructed that improvement in the students can easily be gauged. Of course, the instruction has to be individual as we seldom find two in the same stage of development.

The class in automobile mechanics has been a very popular one, both men and women being interested. A complete chassis has been purchased for purposes of instruction. The engine and working parts of the car are taken apart and put together before the class, and the use of each part of the machinery is explained. Owing to the generosity of the instructor in loaning the school engines and parts from different makes of cars, also owing to the use of charts, the class has received instruction as to the operation, construction and repairing of several standard automobiles. The lecture method is used hardly at all in this class as the instruction is almost entirely in the form of actual experiment in the mechanism of the automobile. In addition to the chassis a full supply of mechanic's tools is on hand for the use of the class.

The classes in bookkeeping, typewriting and stenography, have proven attractive not only to typists and bookkeepers who wish to renew their knowledge and skill but also to novices in these subjects. The teacher, at the beginning of the term, made a study of the systems of bookkeeping and filing used in the mercantile and manufacturing establishments in Port Hope and built up her course on the basis of what she discovered. Actual office methods and procedure are reproduced as far as possible, thus keeping the course entirely up-to-date and efficient. In typewriting and stenography the training is given by actual practice. Next year we aim to have a course of lectures to be given at regular intervals to the students in commercial subjects by prominent business men, bankers and manufacturers in the town.

Port Hope Collegiate Institute.

In home nursing and first aid we have a graduate nurse of experience as teacher. For equipment we provide a hospital bed with spreads, first aid kit, and various sick room utensils. The essentials of sanitation, diagnosis and treatment of the sick are taught, and, where possible, practical demonstrations are given in illustration of the various things to be done in the sick room. Students are also trained what to do in cases of emergency as in fracture, hemorrhage, drowning or poisoning. This course has proved especially useful to mothers and housekeepers.

As for millinery and dressmaking, we find that these are very popular subjects, having an appeal to women in general because of the possibility of economy in the home sewing. Sewing machines, electric irons and ironing boards form the equipment for these classes. Students start by learning stitches and doing simple sewing. Then as skill develops, more advanced work is attempted until eventually, the finished article, be it hat or dress, is turned out. Owing to the fact that the apprenticeship system in dressmaking seems to be dying out here, those who wish to learn this subject naturally come to our school, where they can learn under practised and efficient dressmakers.

So successful has this evening school become that the school authorities are now talking of establishing a day technical school, and building a handsome addition to the high school to accommodate the students' day and evening classes. It is hoped that by establishing day courses in agriculture, metal working and wood working, automobile mechanics, home making and home economics, etc., many students would be attracted to this school from the surrounding country. Whether this plan is to be adopted remains to be seen, but mention of it is made to show how extensive a hold the evening technical school has obtained as an educational institution in Port Hope and how the idea of technical education has become firmly established here.

News From the Welding Field

Commercial Welding on High Pressure Boilers

Eliminate Guess Work—Weekly Test of Operator's Skill and Progress—Choice of Gas or Electric Process for Certain Classes of Work—Best Method of Applying Patches

By EDWARD H. HEIDEL

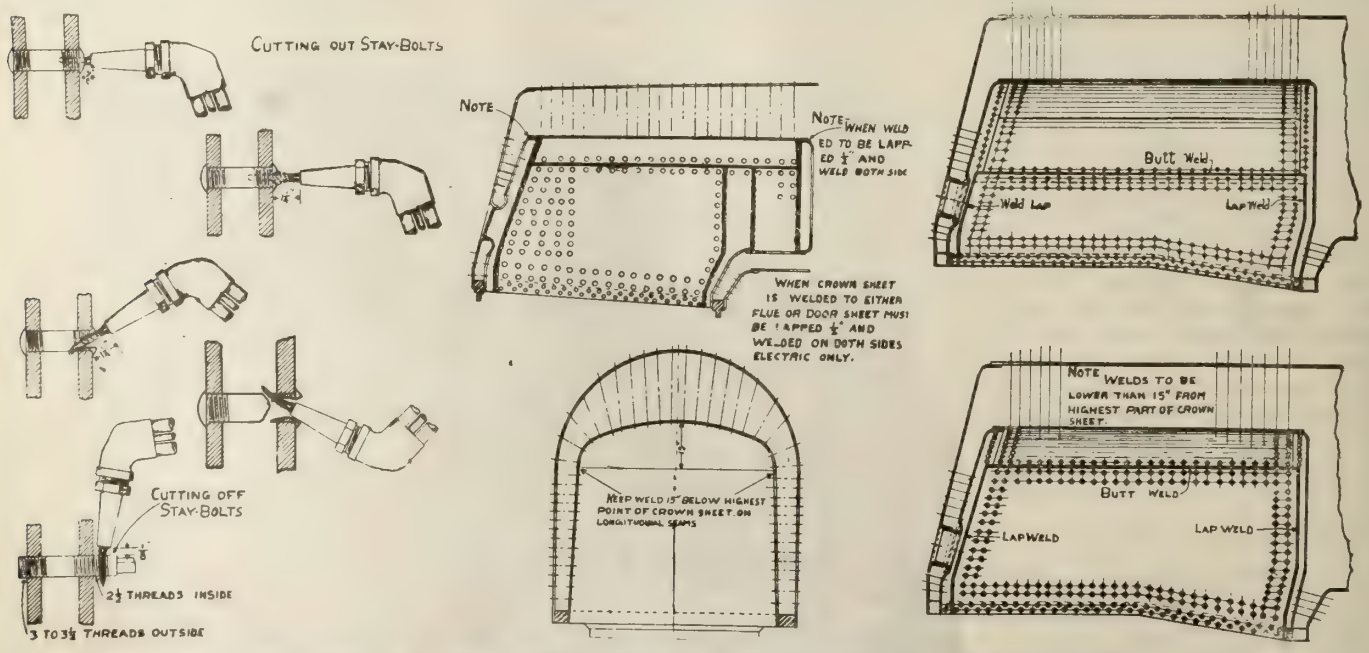
FOLLOWING THE welding of flue sheet patches, described by the author in the first part of this article which appeared in March 23 issue, he continues:

Top or bottom half of back flue sheet may be renewed, care to be taken to see that line of weld clears all braces and does not fall through arch tube holes. Cracked flue sheet bridges may be welded after the flues have been removed from that area by having the cracked bridges properly "V'd" out and welded. Allow the sheet to become cold after welding each bridge before starting another. Weld on both sides. Gas preferred.

Stoker Tubes

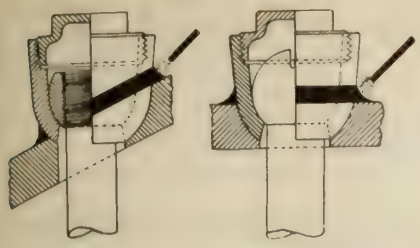
Where stoker tubes are to be applied, sheet is first marked off and cut on a 45-degree bevel with gas cutting torch. Tube then set in allowing ⅜" on each end to be belled out. Tubes are then tacked in four places and welded from the bottom up, on both inside and outside.

Conclusion of paper read before the February meeting of the American Welding Society, Chicago Section. First part appeared in March 23 issue.



Application of crown sheets should be considered new construction and sheet so designed that line of weld will be lower than 15" below top of crown sheet. When crown sheet is welded to door or flue sheet it must be lapped ½" and welded on both fire and water side. Carefully fit all sides using standard gauge, tack every 12" when clamps should be removed and welding completed between tacks. Where possible reinforce from both sides.

Reinforcing Mud Ring Corners



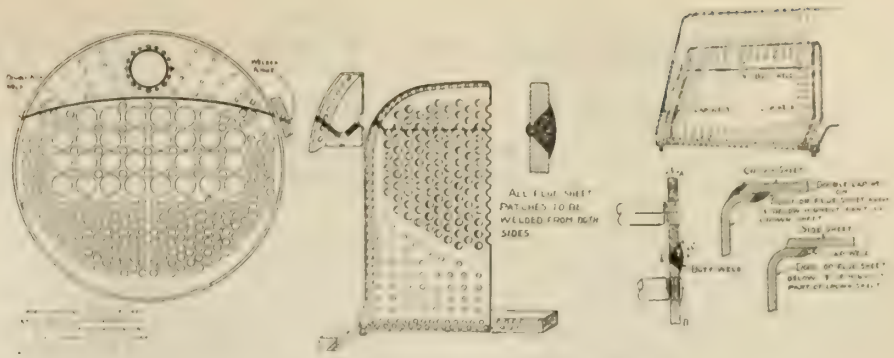
It is considered a good practice to reinforce mud-ring corners inside and out as engines go through shop for classified repairs. Before welding, sheet should be clipped clean and free from oil, dirt or other foreign substance. Corners should be caulked before welding commenced. Metal applied should extend at least 6" beyond corner of ring and up about 8" inside and outside according to conditions. Seams in the firebox can be reinforced in the same manner, first cleaning and caulking seam, then building reinforcement to height and width of sheet welded upon.

Patches may be applied to all sheets in the fire box with the exception of crown sheets. In applying patches to back flue sheet, line of weld must be lower than 15" from highest part of crown. Not more than two patches to be applied to any one sheet. When further repairs are necessary, entire new section to be applied, large enough to eliminate the two old patches. Crack in side or door sheet over three staybolts should not be welded, but a patch applied. Avoid vertical welds in side sheets except at flanges. Fit patch using standard gauge, tack every 12". Start welding at the bottom, working up on side half way, returning to the bottom, working up opposite side to center.

It is good practice to apply patches in side sheets with a circular or elliptical shape, with a DISH pressed in about ¾". Patch held in place with machine bolt through every fifth hole, staybolts butted against patch and bolts placed in center of patch with nuts on the side of welder, with which patch is to be straightened as welding progresses. Staybolts butted up against patch from

Left—Cutting stay bolts. Centre—Welded fire box, combination type. Right—(top) half side sheet weld; (bottom) full side sheet weld.

Electric welded flexible sleeve.



the outside must be turned back or loosened as soon as welding reaches that point in order to remove stresses when weld is contracting.

Half sheets are recommended instead of patches when making repairs. When repairing fire boxes, a number of small adjacent patches will not be applied, but the defective part of sheet should be cut out and repaired with one patch. This refers particularly to round house and running repair work.

Welding Flexible Sleeves

Holes are first cut or drilled in ou side sheet, the size depending on type of sleeve used, 1″, 1½″, 2″, 2⅜″. H les are then counterbored approximately 3/16″ wide at seat to insure proper alignment of sleeve with bolt. It is good practice to bolt motor in place when counterboring at a greater angle than 10 degrees. Do not use oil or lubricant of any kind as this will interfere with making a good weld. Before beginning welding of sleeve, sheet should be cleaned of scale, oil or foreign substances; sand blast preferable. Line up sleeve with bolt end with special tool made for this purpose, which a so holds sleeve to seat while welding.

In welding sleeve to sheet which c nsists of forming a light bond of metal or bead at point of angle as a seal, only sufficient metal to prevent leakage should be applied as the strength and security of the bolt does not depend upon the weld. Care should be taken at the beginning and ending of bead, which can be overcome by lapping weld so as to avoid pin hole.

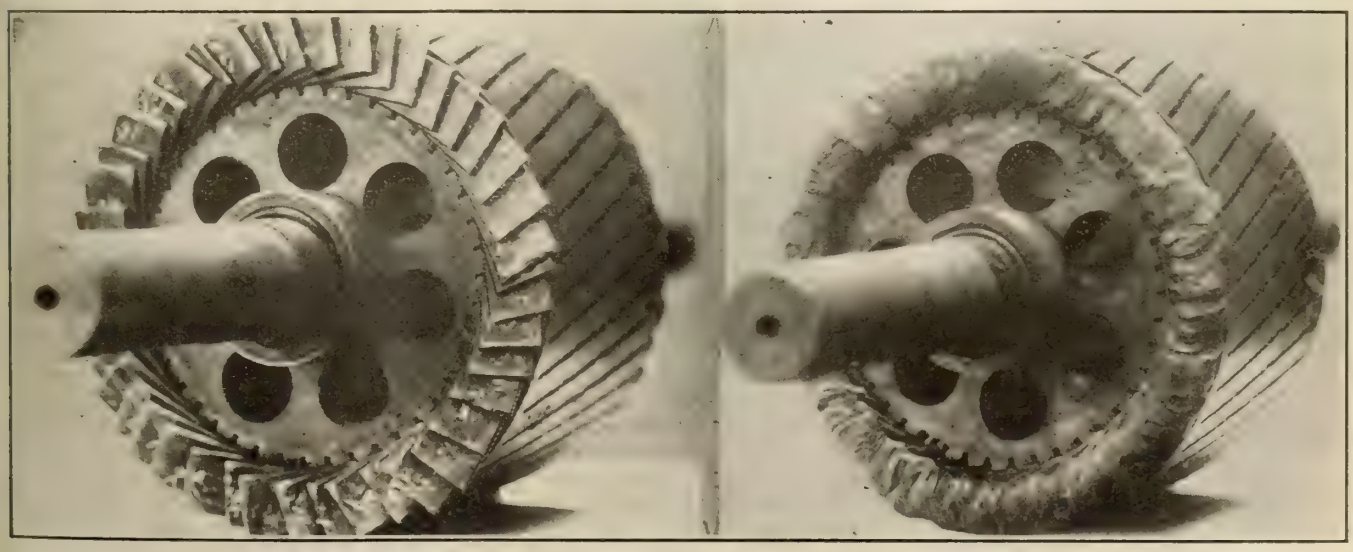
Left—Front flue sheet. Centre—Flue sheet patch. Right—Welded fire box.

Broken Mud Ring

When the mud-ring is broken, sheet in firebox should be cut between first and second row of staybolts and wide enough to work torch or electrode. Should there be any question as to the depth of length of crack, ring can be heated up dark red and allowed to cool when crack will show up very distinctly.

WELDING INDUCTION MOTOR COPPER

By Fred E. Rogers



Oxy-acetylene welding has been applied with success to the "short-circuiting" copper strips or bars of induction motors, making a marked improvement in construction and efficiency of the rotor, and motor as a whole. The rotors, made up of sheet steel disc stampings mounted on a shaft, are "wound" with bare copper strips or ribbon wire set in slots punched in the periphery. The ends of these copper strips have heretofore been joined in a continuous ring at each end by soldering, generally. A more or less common practice is to mortise the strips into copper or brass end discs, and solder them to make a perfect electrical joint. The objection to soldering is the liability of the solder to fuse when the rotor becomes overheated and fly out, thus reducing the efficiency of contact.

The Eck Dynamo & Motor Co., Belleville, N. J., recognized the value of oxy-acetylene welding on this copper work. The copper strips inserted in the slots, are bent over at right angles, lapping one upon another, shutter fashion, as shown in Fig. 1. The overlapping ends are welded, using pure copper filling rod to reinforce and increase the thickness of the joints. The welded job shown in Fig. 2, has a ring of solid conducting copper fully 50 per cent thicker than the strips, and the conductivity is raised to over 100 per cent.

Comparative tests of soldered copper and welded copper show that the efficiency of the motor with welded bars is increased about 15 per cent for the same temperature rise of 50 degrees C. This means that a motor of a given rated horsepower with soldered connections may be rated at 15 per cent more when the rotor windings are welded.

The cost of welding is in measure offset by the elimination of the copper end discs which are no longer required, it being estimated that the saving in copper on some motor sizes balances the cost of the welding gases. The time of welding both ends of the rotor shown in the illustrations was about 24 minutes, or 12 minutes for each end. The welding was done with a No. 616 Manufacturers torch, using a No. 5 tip.

Author is engineer of the Davis-Bournonville Co.

Armature before and after welding.

Manufacturers Views On Adolescent Act

Technical or Night School Favored by Some—Good Advice Given to Boys on Entering Plant—Temporary Hardships May Result—Suggest Better Grade of Teachers

IS AN attempt being made to over-educate the youth of Canada? Will the new Adolescent School Act hamper the manufacturer, or should it have come into force long ago? These, and other thoughts regarding education came to our mind, and believing readers would be interested in the viewpoint of Canadian maufacturers, we made it a point to ask these men for their opinion on this very important matter.

Wm. Inglis, president of the John Inglis Co., Toronto, says that he has never heard tell of anyone getting too much education whether technical or otherwise, but he believes that there is a tendency for young men and girls to go to school until they are into manhood and womanhood, and then start out to learn a trade or a business when they are so matured that they require journeyman's pay to keep them.

Interest in Work Essential

"I do not think any one should start to work under sixteen years of age," he continues, "and if they have a good common school education and are interested in their work in such a way that they can go to the technical school or common school at nights for the betterment of the business they are interested in, I think they will probably learn more in this way than they would going to school until they are twenty.

"When we take boys on at our plant," concludes Mr. Inglis, "we try to impress upon them the necessity of such education, as we do not want to see them stick to the trade for the balance of their lives as they only become machines and not human beings, and as there is lots of room at the top in any business, I think if the boys and girls are taken hold of, well schooled and looked after, it is not only better for the manufacturer but better for themselves."

George A. True, president of the Northern Crane Works, Walkerville, is in favor of all the education that can be given. He believes children should be allowed to stay in school until 16, but as he remarks, all children are not alike.

Supply of Labor Limited

C. W. Sherman, president of the Dominion Foundries & Steel Co., says that they find it difficult, in fact almost impossible, to get any English speaking boy or man to do the rough work incident to their business. "We always have to resort to foreigners," says Mr. Sherman, "and it is getting so that our supply of labor is limited and expensive, particularly as there is quite a restriction on this class of people entering Canada.

"I left school when I was fifteen years of age," concludes Mr. Sherman, "and at that time I had sufficient education to carry on without much difficulty."

R. M. Hamilton, of the Canada Machinery Corporation says that the only youths they employ are apprentices, but that he sees no reason why boys of sixteen years of age with a previous experience in practical work, however superficial it may be, would not be better than boys who are younger, and who have had no shop work of any kind.

Will be Good Long Run

T. A. Russell, president of the Willys-Overland Co. does not believe we are over-educating the youth. "When an important change is made in any long established custom," says Mr. Russel, "you generally find that the conditions are worse before they are better. It may be that the change, just at the moment, by the enforcement of the Adolescent School Act, causes some dislocation and hardship without corresponding advantage. I cannot but feel, however, that manufacturers and society in general, must, in the long run, benefit materially by raising the standard of education of the greatest possible number of our citizens."

Another prominent manufacturer, who prefers that his name be omitted, says he agrees with the Adolescent Act, because he feels that to have the education of the youth of the country continued until they are 16 years of age will have a good effect.

"We don't employ youths under 16 in our business except in exceptional cases. It doesn't seem as if it would be wise to take boys from school earlier than that. The exceptional cases might be those who are found practically incompetent of a higher education and where it is necessary that they assist possibly a widowed mother in gaining a living. I would imagine that whatever may be found impracticable in the Act will be removed, and it certainly would pay everyone interested to give it their consideration."

"Judging from the results, I should conclude that the trouble is not one of over-education but of under-education," says another well known manufacturer.

"In my opinion," continues the gentleman, "the class of people obtained for the teaching staff is by no means as good as it might be, or should be. Such elementary subjects as arithmetic, spelling and the use of good English are improperly taught because the teachers are not sufficiently well acquainted with them. The remedy would appear to be to pay better wages and attract a better class of teacher. If this were done, there would be no need for young people continuing at school after the age of fourteen except for the study of technical subjects."

An entirely different viewpoint is expressed by another manufacturer who says, "I am thoroughly satisfied that an attempt is being made to over-educate the youth of the country by spreading their studies over too wide a range instead of concentrating on a fixed number of essentials, leaving the student as he develops into maturity to do his additional reading along these lines to which his mind is naturally attracted, or his talents specially adapted. Instead of that we have in Manitoba an attempt to compass a smattering of the whole range of human knowledge, with the inevitable and obvious result that the youths are not being grounded in any single line of studies. I attribute that in Winnipeg to the fact that there are very few men on the school board, or connected with the department of education, who have had anything but a public school education themselves, and they are attracted by the glamor of a lot of names of subjects of which they themselves know nothing but the names.

"As a graduate engineer myself," concludes this gentleman, who is president of a well known firm, "I have seen the same tendency in engineering. There does not seem to me to be any question but that improvement could be made in this matter."

Common Labor Required

"I believe," says John Leitch, managing director of the Collingwood Shipbuilding Co., "that every boy and girl should receive a good general education but that the majority do not require to be highly trained. Common labor is required everywhere, especially in a new country like Canada, and it stands to reason that the laboring class does not require to be instructed in highly technical matters. All our industries, however, require skilled men of good education and as far as I have seen, the youths of Canada at present are not over-burdened with education on technical subjects.

"In Great Britain and Germany a great amount of attention is and has been paid to the education of the apprentices. In many works the more brilliant are required to spend only a portion of their time in the shops and the remainder of the time in attending university or technical college, this during the day, not at night. Formerly, apprentices in Great Britain were encouraged to attend evening classes while they had to put in all of their time in the plant during the day. They think so much of technical education now that they have changed this system, to give the boys a chance to study during the day.

"Naturally a great number of the ap-

prentices are not studiously inclined and in each plant it is only a few of the brighter and more ambitious apprentices who attempt to qualify for the college courses, so that there is no fear of the plants being over-run with young men who have taken degrees. The matter really adjusts itself.

"Regarding the Adolescent Act, if children were compelled to stay at school until they are sixteen years of age, I do not think they could possibly be over-educated. The regulations might, of course, be a hardship to a great many people who require their children to work as soon as they possibly can, and latitude might be given to such people. Other things being equal, I certainly am of the opinion that children should remain until they are sixteen or over."

The remaining opinion is also from a prominent manufacturer, and here is what he says. "The Adolescent Act not only hampers manufacturers, but it hampers all in the community who pay taxes, or who have work to do.

"At the beginning, I would lay down the principle that every child ought to be educated up to that point where it ceases to absorb a reasonable proportion of the information offered, or where the probability of such information being useful in after life becomes relatively slight. This would not be a difficult system to operate, for, by a combination of competitive examinations and teachers' grading, only a certain proportion of those attending one grade would be permitted (also compelled) to pass on and attend the next grade. The present entrance examinations, also the matriculation, pass all above a certain quality. A similar culling out each year, based not on a certain pass percentage of marks, but on the individual's ability relative to all others of the same age in the province, would ensure to the capable child an education up to senior matriculation. Suppose for example that 25 per cent. were turned down each year after 14 years, or the entrance age. At each succeeding year there would be carried forward for further education 75 per cent., 56 per cent., 32 per cent., 24 per cent., and 18 per cent. of the original class.

"The cream of the youth of the country would be educated, and the mentally slow, the lazy, those unwilling to think, would be started to work with an educational equipment in proportion to their ability or inability to use it. There is a lot of low grade work to be done in this or any country, and there are a lot of people born every year with low grade brains. This is not a matter of argument, it is a positive fact. Our educational institutions should be so arranged that the low grade work of the next generation will, (so far as it cannot be done by machines) be done by the citizens of small mental calibre. Let the thinking be done by those capable of thinking. Look at the condition of some European countries where the thinking, such as it is, is done by the proletariat, while the intelligencia, if not killed, subsist on odd jobs.

"The question of whether a rather dull son of a rich man should be put out of school for his dullness is a mere detail of operation. Perhaps it would be better to have him out of the class and away from his mental superiors. His father has a right to buy him an education, certainly, but let it be in a private school or with a tutor. The Adolescent Act keeps all to one level," concludes this manufacturer, "it keeps the most stupid in school for two absolutely wasted years where they learn only to be dissatisfied, and it spends on them the money (taxes) which ought to have been spent on providing the poor but highly intelligent neighbor by his side with not two but four or five years of free education."

INTELLIGENT CHOICE MADE BY STUDENTS

INCREASED OUTPUT BY MEANS OF TURRET LATHE

(Continued from page 41)

is finished all over to the dimensions shown in Fig. 4 at the rate of eight a day. With the engine lathe it required approximately 4 hours for completing each pulley.

Large Pipe Flange

An interesting turret lathe job is shown in Fig. 5 and 6. It is a large cast iron pipe flange, faced, bored taper, and threaded to take 12 in. pipe. It will be noted that the pilot bar is held rigid in the turret while the tool holders for boring and threading are designed for horizontal movement at right angle to the lathe spindle, the travel being controlled by the taper attachment at the rear of the machine.

Motor Cylinder

A good example of the possible range of the turret lathe is shown in Fig 7. By means of special holding fixtures secured to the face plate of the machine the work can be placed in position on comparatively short time. The piece being machined in a Wolverine motor cylinder of cast iron, 8½ in. bore, and weighing when finished 228 lbs., the metal removed being about 48 lbs. The cylinder is bored, faced on both ends and recessed in a little over 40 minutes —one-third of the time formerly taken.

These are only a few examples showing the possibilities of the turret lathe as adapted to the machining of heavy equipment in reasonably large quantities.

The city council of Edmonton has authorized the expenditure of $150,000 for power plant extensions and improvements.

Physics room at London technical school.

Practical Ideas for Shop Executives

TAPER REAMER FOR DRILL PRESS

By V. Coffin

Where large numbers of holes are to be reamed for taper pins, a saving can be accomplished bo h in labor and reamer costs, by making a one flute reamer to be used in the drill press. This applies particularly to the smaller sizes, where the reamer is more apt to be broken by hand usage. We have a reamer in use at present that has reamed over 2,000, No. 2 taper pin holes, these assemblies being of cast iron and steel. After selecting a suitable piece of steel and machining out reamer blank, it is necessary to provide a fixture that will not allow the blank to be sprung while the quarter section or one flute is being milled out.

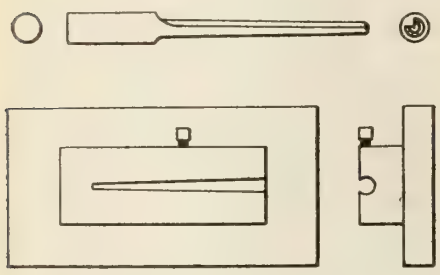

Fig. 1.—Taper reamer for drill press.

Tee shaped casting Fig. 1, is bored and reamed by standard taper pin reamer, and top of casting is cut away until part of reamer blank when inserted would be exposed. By inserting set screw at the side it would prevent the blank from rolling during milling.

After section is removed, reamer should be carefully hardened and ground to size, and after leaving usual land at cutting edge, reamer should be backed off for a quarter of the diameter to provide clearance. Too much will cause it to dig in. Reamer can be sharpened when dull by grinding on the flute. When using the reamer it is lifted and brushed frequently with oiled brush to clear cuttings from flute, and should be run at a moderate speed. Provided with rigid fixtures and careful handling it will increase production.

CLEANING SPECIAL TAPPED HOLES

By Donald A. Hampson

One of the meanest jobs that comes along is the bruised thread of a tapped hole when that thread is a special. It is to be expected that no one will have taps for such threads. If the damaged thread would only appear always in a convenient shaped piece, the task would not be so bad, but invariably it is in some piece that is so awkward to swing in the lathe that it would pay to scrap the piece if another were obtainable.

Sometimes the piece can be grasped in a vise and an inside thread tool, held in both hands, used like a scraper to clean out the thread. This is a slow, bumpy job but it is well worth trying. As long as the thread is reasonably fine—say, not coarser than 16—this method is good. The only bad feature about the thread tool method is the difficulty of getting the first complete thread scraped out—the starting of the thread—and this trouble may be avoided by making a special tool with the point turned the opposite way. Such a tool enables the machinist to scrape from the inside out, from a good portion of the thread into a bad, and is often the salvation of the job for the first thread is almost certain to be one of those bruised.

Another good method is the making of a tap. No, not an expensive tap or a long drawn out job. Take an ordinary piece of steel and cut on it a smooth thread of the same lead as the bruised thread and as nearly the full size as can be determined. After threading this piece, turn the end tapered like a taper tap and then file one flute in the end. This "tap screw" is to be run in the hole to straighten up the damaged threads, the idea being that it will catch the threads as the point enters and as the fit grows tighter the one flute will scrape its way in and the piece line itself up as the poor thread is corrected. And in a majority of cases, it does the work in good shape. If the part happens to be brass, the steel tap screw may be used as it is; if it is some ferrous metal, it will be necessary to case-harden the tap. By making the tap on the end of a bar, it is possible to repair threads deep down inside, where they could not be reached by other methods.

WEIGHTS OF METAL BARS

By W. F. Shraphorst

The accompanying chart provides a convenient method of determining the weights of solid or hollow metal bars of ordinary dimensions. By means of a straight edge placed across the chart as shown by the dotted lines, the weight may be easily found. The chart shows the result for a bar of mild steel 2 in. in dia. and 30 ft. long. The table herewith shows the weight of mild steel to be 487 lb. per cu. ft. By connecting the 2 in. column A with the 30 in. column D, and working back from the intersection on line B over the 487 in column E, the point where the straightedge cuts the column G will be the desired weight; in this case 320 lbs. By calculation the weight is found to be 318 lbs.

The weights of common metals mostly used in industry are as follows:

Aluminum .. .. lbs. per cu. ft.	165
Brass	534
Copper	556
Wrought iron	485
Lead	710
Nickel	537
Mild Steel	487

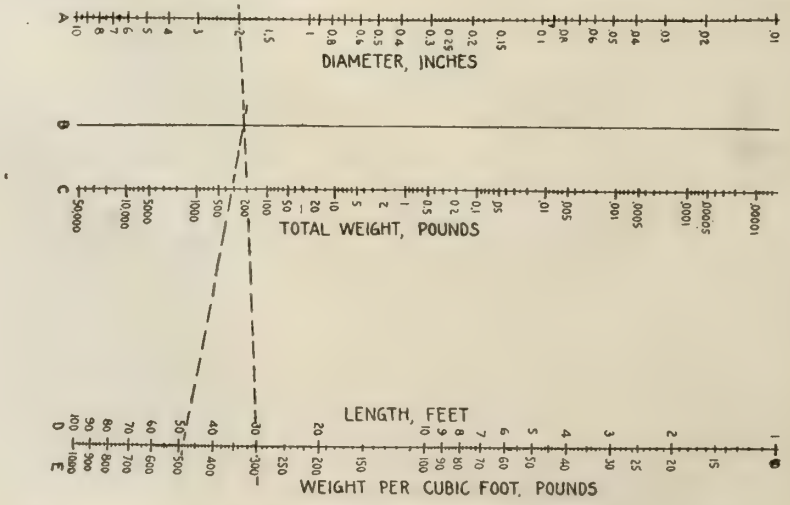
The chart may be used vice-versa if desired. If it is required to know the length of bar that will weigh a certain number of pounds the reverse process would be necessary.

For hollow bars the same method would be followed, calculating the inner and outer diameters and deducting the former from the latter.

SUB-PRESS NOTCHING DIE

By A. J. Q.

The die shown in the accompanying sketch illustrates a tool designed for notching angles in sheet metal. The angles in this particular case being 30, 45, 60, 90 and 135 degrees. The tool is of the sub-press type, and does not



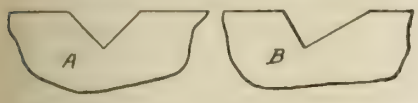


Chart for finding weights of metal bars

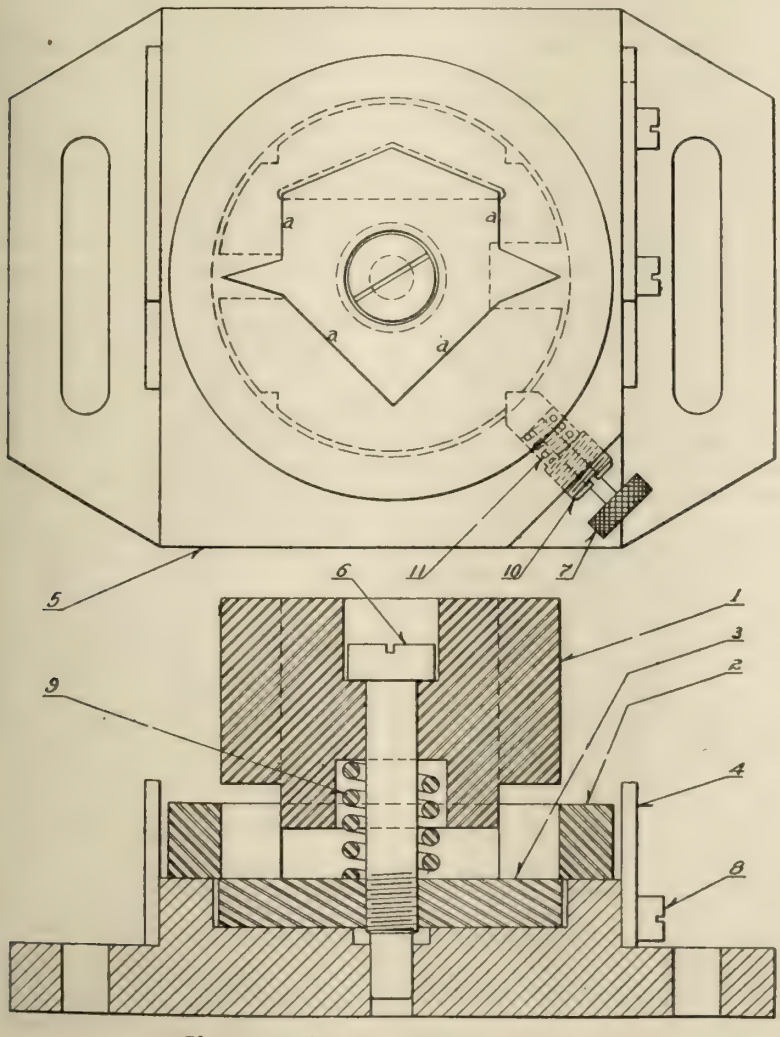
require to be fixed in press or other machine. The die may be revolved to any desired position, an index pin being provided for this purpose. This permits the notch desired to be brought to the front of the machine. The index plunger (7) is pulled out to allow the die block to revolve. On the side of the shoe are two adjustable stops or gauges that are set to give the notch required. By regulating the position of these stops the centre line of the notch may be altered to suit varying conditions, as shown at A and B.



The construction of the tool is shown by the drawing. The punch is made in one solid piece and, in this instance, has five different angles. The punch is piloted into the die, fitting closely at the four faces (a). This not only guides it vertically but eliminates shearing of the cutting faces. The punch and die are held together by the bolt (6), and spring (9) is strong enough to strip the stock. Ample space is provided between the punch and the die for the insertion of the stock. The end of the clamping bolts forms the bearing on which the punch, die and index plate revolve. The locking pin and gauges are carried on the die shoe. The die need not be fastened down unless desired.

With certain modifications the same die may be adapted to punching holes of different diameters, stamping or stencilling letters, etc. The die here described has been used successfully for some time.

EMPLOYEES AS SALESMEN

A plan recently adopted in a local shop manufacturing a domestic machine, has done much toward creating more business for the company, the employees directly gaining increased employment. It was proposed that the employees should have the privilege of receiving a salesman's commission for every order brought in. This naturally caused some enthusiasm among the more ambitious of the men, who with their inside knowledge of the machine, had the advantage over the average salesman, in that they can intelligently talk machinery and inspire confidence in the prospective buyer who generally lacks this knowledge. Believing results can be obtained in this way toward increasing business, the employee utilizing his spare time in hunting up prospects, will take a much greater interest in the product manufactured. This proves a valuable asset to any firm, as an interested employee means increased efficiency, costs being lowered through less wastage of material. A satisfied staff of workers employing the personal interest cannot be bought by money alone, and when this co-operation is attained it will go far toward building up future business of any company.

Plan and sectional view of sub-press notching die.

PROVING MULTIPLICATION

In performing long problems of multiplication errors frequently occur. This is particularly true when the work is hurriedly done in checking up dimensions in the shop or drawing office. The proof here given has been used by the writer for many years and, although not a new method by any means, may be of interest to other readers. The method is generally known as "casting out the nines." Take for example the problem here shown.

3·6942	3+6+9+4+2 = 24
46·375	2+4 = 6
184710	4+6+3+7+5 = 25
258594	2+5 = 7
110826	7×6 = 42
221652	4+2 = 6
147768	
171·3185250	1+7+1+3+1+8+5+2+5+0 = 33 3+3 = 6

Like many other rules the work is easier than the explanation. The sum of the digits in the multiplicand is found to be 24. The sum of 2 and 4 is 6. This is the factor for the first row of figures. For the second row (multiplier) the factor is found to be 7. The product of these two factors is 42, the sum of which is 6. The digits in the product are dealt with in the same manner, the result being 6. This shows that the work is correct. If the results differ it indicates that an error has been made. By confining the work to each line the error can easily be located. There is one way in which this rule may be defeated and that is by making two errors, one of which compensates the other. This, however, will rarely occur.

LUBRICATING WORK ON MILLER

By J. H. R.

For lubricating milled work, oil, pure or soluble, or soapy water is generally used, but this does not apply to cast iron or brass. Where milling is not a regular operation, a cooling lubricant can be dispensed with, but in most cases it is to be preferred. It should be liberally used because it does more than merely lubricate the work. Plentiful oil makes easier the formation of a smooth surface, and helps to free the teeth from chips and cuttings. Milling cutters, and especially those of high-speed steel, are expensive tools, both to purchase and to maintain in a state of efficiency. It is important, therefore, that they should only be used for work which are designed to do. Where carbon steel milling cutters are used, care should be taken to see that the correct temper is given for the work the tools have to do.

Conditions Have Improved in Many Quarters

Reports From Various Cities Are Very Encouraging—Sugar Industry and Textile Trades Are Busy—Automotive Trade Shows Increased Activity and Iron Working Industries Are Picking Up —Several Promising Industrial Prospects

"THE FORT William Paper Co., are making additions to their plant," says W. Webster, secretary, Fort William board of trade, "A sluice is being constructed from Lake Superior in front of the plant site to the grinding mill, for the purpose of facilitating the movement of pulp wood from the booms in the lake to the grinders. A sluice-way 2,600 ft. long is projected out into the lake, considerably elevated at the outer end, water is pumped from the lake into the sluiceway and the pulp wood floated to the grinding mill. This will effect quite a saving in handling time."

"Industrial conditions," says R. E. Armstrong, secretary of the Saint John board of trade, "along some lines, are showing an improvement in this section, but basic industries, such as lumber, lime and fish, are still in a semi-comatose state. There is a feeling, however, that with the opening of Spring there will be a revival in all of these lines.

"There is little building construction going on as yet, outside of the erection of schools and necessary public buildings of this character. Many of our people are anticipating the construction of new residences during the approaching summer. One of the busiest concerns at the present time is the Atlantic Sugar Refineries. This industry has been doing quite a large export business, shipping in the vicinity of about 3,000 tons per month of refined sugar to the United Kingdom, France, Italy and other overseas points. Spice-making is showing improvement, at the spice mills of G. E. Barbour Co. and the Canada Spice and Specialty Mills.

"The brush industry is bristling up a little and will soon be back to normal. Cotton manufacturing is also showing an improvement. The nail manufacturing business, which is one of our chief industries, is not very active as yet, but with a revival in building conditions in Canada and throughout the world, this branch of industry will soon depart from its quiescent state.

"There is likely to be an improvement in brick manufacturing shortly. The Lee brick-yard, which is one of the most promising in this section, has lately passed into the hands of an energetic company.

"Metal industries are beginning to recover slowly. The McAvity plant, which was busy on shell-making during the war, has entered upon the manufacture of iron piping for water distribution. The city is planning some street-paving and water extension for the coming summer.

"The winter port has had quite a busy season. While general cargo shipments have not reached the total of last year, a very decided improvement has taken place in the export of grain, the shipments to date amounting to 221,318 tons, as against 134,902 tons last winter. Potato shipments to Cuba have been larger than for several years. This winter has also witnessed the return of live stock exporting. Three cargoes of cattle have gone forward this winter, being the first shipments since 1912 from here. It is expected that Courtenay Bay development work will be resumed within the next month or two. General business is on the upward move with still brighter prospects ahead."

J. H. Brosseau, secretary-treasurer of the Sherbrooke, Que., board of trade, says, "Our industries at the present time are looking better, particularly our textile industries, such as silk, wool, and cotton. Our jewelry manufacturing firms are finding business rather quiet but at this season of the year it is generally expected. The same may be said of our mining machinery, which is no doubt due to the strike of the coal mining region of Cape Breton, also on account of the dulness of the copper market, thereby causing very little activity in the copper mining region of British Columbia, but as confidence is improving, we expect in the near future a change for the better, as the copper and coal situation must improve when general business begins to feel the activity of all its branches."

J. A. McGibbon, secretary of the Oshawa board if trade, says that business conditions generally are improving. He continues, "A marked improvement is noted in the General Motors, and the factory is now working overtime and new hands seem to be taken on each day and the staff materially added to. In consequence, other factories are also increasing their output, this applies more especially to Pedlar People, Ltd.

"During the past month, the factory of the Thornton Rubber Co., was destroyed by fire and there are rumors that Col. Phillips, a son-in-law of R. S. McLaughlin, is going to operate a wood-working plant there. The Spring and Axle Co. are now in operation, and Mr. F. C. McCulloch has purchased the old Parks foundry and has booked large orders for brass works and intends to commence operations at once.

"There is a good deal of business construction being done in the line of stores, etc., and the lack of houses, has made the local council decide to construct from 10 to 20 new houses under the supervision of the Oshawa Housing Commission. There are rumours that the Fletspar Glass Works will commence operations in the very near future. As a whole the industrial situation is a good deal brighter than at the first of the year."

"Industrial conditions in this City are slowly but surely improving," says H. Westoby, secretary of Guelph chamber of commerce. "The Crowe Iron Works, which until recently were on short time, are now running full time, and several other of the iron industries are either on full time or running four days per week, and all tell me that within a few months they will again be running six days per week. The White Sewing Machine Co. which has recently been extremely slack, has just taken on a new line, the manufacturing of school desks and furniture. They are increasing their number of employees from 60 to 200 immediately, and have announced that by the middle of this summer they will be employing 500 men. The textile and rubber industries are running night and day, and the industrial outlook as a whole is brighter at the present time than it has been for 12 months past. The City of Guelph has arranged a very elaborate program of street paving and other work for the current year, and with the improved industrial outlook, there should be work for every man before many weeks have passed."

George I. Warren, managing secretary of the Victoria, B. C. chamber of commerce, states that the Beech-Aitken Co., who put up canned fruits, etc., have located in Victoria.

Chas. A. Cooke, secretary-manager of the Regina board of trade, says that they have every prospect of a busy building year, largely residential, with several commercial structures, though, he adds, a great deal depends on the outcome of negotiations at present proceeding between employers and employees in the construction trades.

F. Maclure Sclanders, commissioner of the Border chamber of commerce, says that industrial conditions throughout the border communities have been much better and brighter than they had any logical reason to expect, when the magnitude and duration of the recent war is remembered. He mentions that conditions have steadily improved since the start of the year, and that they have no reason to complain. He adds, "We have good reason to be hopeful and encouraged, and we have weathered the storm very satisfactorily indeed. True, we are not nearly so busy as we could be, save in a few instances, but we are not worrying. The worst is over; the best is still to be.

"As to new industries—these are coming in steadily and quietly: — two quite recently. In all, we now have 238 operating industries here. People further East do not realize just what is

(Continued on Page 66)

New Things in Shop Equipment

CHAMFER GRINDING FIXTURE

A fixture for holding die chasers while grinding the chamfer has been developed. With this attachment it is possible to obtain the exact angle and length of chamfer on the complete set of chasers. The supporting portion is adjustable and graduations provide accurate setting for any desired length of chamfer, either on the milled or tapped style of chaser. Guiding key and stop, which may be locked, governs the position of the chaser in respect to the grinding wheel. All sizes of chasers may be ground on the one fixture. The Device being placed on the market by the Geometric Tool Co. of New Haven, Conn.

OFFSET DRILLING ATTACHMENT

An offset attachment for drilling, milling, countersinking or counterboring port holes in such equipment as pneumatic tools, etc., from the interior of the cylinder has recently been developed. The arm is made especially rigid for heavy duty work. The offset arm and transmission members are made of vasco-vanadium tool steel, heat treated by the Bellis process, and accurately ground and lapped after hardening. All parts are closely fitted to obtain extreme rigidity of cross section. The attachment is made to fit any standard type of drill press. A full assortment of drills and counterbores are supplied with the device. It is made by the Harris Engineering Co., of Bridgeport, Conn.

PORTABLE ELECTRIC DRILL AND GRINDER

A portable electric drill having two speeds has been recently placed on the market. The two speeds permit the tool to be used in a dual capacity, namely that of drilling and of grinding. It has a drilling capacity of from ⅛ to ⅝ in. in steel, and is supplied with a 6 by ¾ in. wheel for grinding purposes. The slow speed is used for drilling and the faster for grinding. The motor is of ½ h.p. and is capable of operating on either direct or alternating current, of the same voltage. A quick make-and-break switch in the handle controls the motor. The machine weighs about 18 pounds. It is manufactured by the Wodack Electric Tool Corporation of Chicago, Ill.

TUBULAR FRAME DRAWING TABLE

A line of drawing tables, in which the frames are tubular, has recently been developed and placed on the market. The design gives all the rigidity of other types of construction and is very much lighter. The table can be raised till it is forty-four inches from the floor when in a horizontal plane. A hand-wheel operating an elevating screw is employed to do the lifting. The table can be clamped when the proper height has been obtained. It also can be tilted from the horizontal to almost a vertical position. Large corks are inserted in the feet of the stand to prevent floors from being marred, and also to eliminate the tendency to slip around. A combination drawer and tray can be attached to either the left or right hand side of the frame, and can be clamped at any convenient height on the standard. The drawing table is manufactured by Hoffman Drawing Stand Co., of Rochester, N. Y.

MACHINE TIME CALCULATOR

A calculator that has been designed for use in computing time required for operations performed on machine tools, whether these tools be of the revolving or the reciprocating design, has been placed on the market. It consists of cylinder enclosed in an aluminum case, with a slide rule of special design attached to an extension of the base. When used in connection with revolving work or tools, on such machines as lathes, boring mills, drilling or milling machines, the cylinder has tables giving the number of r. p. m. made by work or tools of diameters from ¼ in. to 10 ft., at all ordinary cutting speeds. In connection with planers, shapers, slotters, or other machines having reciprocating tools or work, the procedure of calculating the time is quite simple. The instrument was designed to be used by rate setters, estimators, and others whose duties require a study of machine operation time. The instrument is about sixteen inches long and weighs about three pounds. It is manufactured by the Simplex Calculator Co., of York, Pa.

NEW CIRCULAR MILLING ATTACHMENT

One of the latest offerings in accessories for machine tools is a table that can be fitted to a standard high-speed vertical milling machine for circular milling operations. The attachment is mounted on the regular table of the machine and driven from a telescopic shaft which furnishes the longitudinal table power feed. This means that on the standard milling machine for which the fixture has been designed, thirty-three feeds are available. The circular feed is finally driven through two gears that can be transposed, which doubles up the number of feeds just mentioned. It is possible to operate both the longitudinal and circular feeds simultaneously, which is an advantage on some classes of work. Some of the measurements of the fixture are; diameter of working surface, 10-½ in. maximum height from nose of machine spindle to table, 9 in. ratio of table revolutions to turning of handle, 40 to 1; weight of fixture is 110 pounds. The fixture is manufactured by the Taylor and Fenn Co., of Hartford, Conn. The fixture is designed to be attached to the vertical milling machine manufactured by this firm.

PIPE THREADING MACHINE

A 12 in. threading and cutting machine that can be equipped for threading oil well casing and hydraulic pipe has been placed on the market. The normal range is from 4 in. to 12 in., but may be adapted to cut pipe 2½ in. in dia. The range is accomplished by means of two die heads, each head having only the one set of chasers. The die head or carriage may be moved either by hand or power, one operating lever controlling the traverse in either direction. Automatic safety stops are provided for the carriage travel. The reaming tool is quickly set to position and locked with a lever. The reamer is fed to the pipe by rotating the cutting off feed hand wheel in a counter clock-wise direction.

The machine has a single pulley drive. The variations of speeds, eight in number, are obtained in the speed box, located under the main spindle, by shifting levers on the side of the gear box. The machine is started and stopped through a friction clutch by either one of two levers located at the extreme ends of the head stock. This enables the operator to start or stop the machine when threading or when fitting up flanges. A lever is located midway between the starting and stopping levers for reversing the machine. The chucks for gripping the pipe have three jaws. These jaws are geared and have universal adjustment. They are also self-centering to the pipe. The rear chuck is equipped with flange grips for fitting up flanges.

Is made by the Landis Machine Co., Waynesboro, Pa.

HYDRAULIC MARKING MACHINE ATTACHMENT

Attachments have recently been manufactured for a marking machine which will enable markings to be done in a circle, on the flat sides of cutters, rings, and other similar parts. The object to be marked is placed on a fixture mounted on the table of the marking machine. The top of this fixture is free to revolve on ball bearings. Adjustments can be made to mark to any radius, in order that all markings may conform to the space provided for same on the work. A plain roll die is used and it is held in one position and revolved about its axis by means of a rack

fastened to the side of the machine. As the work is brought in contact with the revolving die, the top plate of the fixture is revolved. A plug set in the centre of the revolving plate, fitting the bore of the work, keeps the latter in the proper position. At the end of the marking stroke the die is returned to its starting position by the return stroke of the slide. The hydraulic operation of the table results in satisfactory marking, regardless of variations in the thickness of the work. The attachment is manufactured by the Martin Machine Co., Inc., of Turner's Falls, Mass.

HAND-OPERATED VALVE FACER

There has recently appeared on the market a hand-operated bench machine for accurately and quickly refacing valves of internal combustion engines. It is being marketed under the trade name of "Peerless valve lathe." The hollow spindle of the lathe is mounted in a single long bearing, the body of which is cast integral with the base. In this spindle is located the chucking mechanism, which consists of two collars having each a three-point internal cam which actuates three pins. When the front jaws grip the valve stem they are locked tight with a nut. The rear jaws are used in the spindle and valve drive. A gear turns the lathe spindle, and, as it turns, the tendency of the jaws actuated by the internal cams, is to bite harder on the valve stem. Thus no locking device is needed here. The spindle of the lathe is bell mouthed in order to accommodate the fillet between valve and stem which is sometimes excessive. Provision is made for locking the spindle when tightening the front jaws. These jaws are tightened by means of a spanner fitting in slots in the collar containing the internal three-point cam. A special automatic feed is provided for the tool. The uniform rate of feed is said to produce a finish that reduces grinding in to the minimum. The machine is manufactured by Steiner Bros, of Lima, O.

HEAT-TREATING FURNACES AND OIL-PUMPING SYSTEM

A double-chamber, semi-muffle heat-treating furnace has lately been placed on the market. Both chambers of this furnace are individually controlled. Thus different operations can be carried on simultaneously. The furnace is underfired, combustion taking place under the floor and the products of combustion pass up along both walls to the arch and then down on the work. The furnaces may be equipped to use either gas or oil or a combination of both. The furnace is not only built with a cast iron casing, but also with a sheet steel casing. In connection with these furnaces, and other types manufactured by the same firm, is an oil pumping system. This system delivers oil at a uniform pressure and free from foreign matter. The foreign matter is removed from the oil by strainers. Spring-load relief valves prevent injury to the system in case the discharge should become clogged. The valves also furnish variations in the operating pressures. A pressure dome dampens the pulsations in the pump, at the same time serves as a settling chamber in which the water and sediment settle before the oil is delivered to the burners. Gauges provide easy pressure readings of the oil. The pumping system is made with a capacity delivering 82 gal. of oil per hour. The furnaces are known as the Stewart furnace and are manufactured by the Chicago Flexible Shaft Co., of Chicago, Ill.

INSIDE MICROMETER CALIPERS

There has recently been placed on the market a set of inside micrometer calipers having five rods, which permits of measurements being made from 3 in. to 8 in. in increments of 0.001 of an inch. It is well adapted for use in determining the internal diameters of cylinders and rings, as well as taking linear measurements, testing the parallelism of surfaces, comparing gauges, etc. The barrel, spindle and thimble are similar in construction and diameter to those employed on outside micrometers. One feature of this new micrometer is the provision of a detachable handle, which may be instantly set to permit of easy reading of the graduations, whether the work is right or left hand. The extra rods make for quick changes to suit the work to be measured. The rods are changed by simply unscrewing one rod on the threaded stem of the barrel, and then screwing the proper rod in place. Each rod is ground square at the hardened end, so as to seat in the proper relation at the barrel shoulder. The point of measurement is fitted with a hardened tool-steel anvil, which is adjustable to lengthen the rod and to compensate for anvil wear. The faces of the anvils are ground to a small radius. Additional lengths of rods can be supplied to special order. The micrometers are being manufactured by the Reed Small Tool Works of Worcester, Mass.

LATHE ATTACHMENT FOR CYLINDER GRINDING

A Lathe attachment, that has been designed for use in small garages, where it is desired to obtain a cylinder-grinding equipment at a reasonably small cost, has recently made its appearance on the market. The device can be attached to any lathe of 14 inch swing or over. The driving motor is mounted in frame of the fixture underneath the grinding spindle. This frame is attached to the ways of the lathe close to the head stock. The motor, that is usually supplied with the outfit, is rated at ½ h. p., and can be driven from any lamp socket. With this attachment is also supplied an angle plate, mounted on the lathe carriage, and to which the cylinder block to be ground is attached. The motor drives the grinding spindle by means of a belt. A chain and sprocket drive is led to the head-stock spindle of the lathe, and by this means the carriage feed mechanism is actuated. This carriage feed is used to feed the cylinder block when grinding. This arrangement permits of all the different lathe feeds being available. The grinding spindle is driven at 5,600 r. p. m. The eccentric throw of the wheel from the dead center is adjustable by a hand screw graduated to 0.0005 in. The angle plate holder will accommodate the largest size six cylinder block, having an inside length of 33 in. Cross movements of the holder are obtained through a screw, and the holder may be raised or lowered by means of two vertical screws. The total weight of the attachment is about 500 pounds. The apparatus is manufactured by the Liberty Tool Co., of Irvington, N. J., and is marketed under the trade name of "Elteco."

HYDRAULIC PRESS

A new 250-ton hydraulic press that has been designed primarily for pressing solid rubber truck tires on or off wheels has recently been placed on the market. The press can, of course, be adapted for many other uses. The frame and top platen are steel castings. The ram area is sufficient to produce the required tonnage with an initial pressure of 2,000 lbs. per sq. in. The pump is of the three plunger type. One plunger is larger than the other two and is designed to handle the low pressure liquid quickly and when the pressure rises over 200 lbs. per sq. in. it is automatically cut out. The larger plunger is 2 in. in dia. and is used to cut out the large plunger. When this plunger is cut the two smaller plungers continue in operation and deliver the higher pressure required for the maximum tonnage. The press is controlled by operating a globe valve located in the by-pass piping, taken out of the main pressure pipe. When the valve is open, the oil or water used as a medium of pressure, is returned to the supply tank instead of being delivered to the cylinder of the machine to apply pressure to the ram.

The tank is of the enclosed type and when desired a compressed air line can be connected to the top of the tank to furnish means of forcing oil or water quickly into the cylinder to move the ram up to the point where high pressure is desired. In cases where air pressure is used for this purpose the pump furnished is equipped with all high pressure plungers. A safety valve protects the press from a careless operator. The bottom platen is 42 in. in diameter and the maximum distance between the top and bottom platen is 37 in. The ram has a stroke of 33 in. The press is manufactured by the West Tire Setter Co., of Rochester, N.Y.

Extreme care should be exercised in the storage of grinding wheels. They should be stored in dry places and be supported on edge in racks. Straight-sided shellac and rubber-bonded wheels of ¼ in. or less in thickness should be laid flat on a straight surface to prevent warpage.

The Passing of a Great Man

SIR JOHN EATON is dead. In all parts of Canada people are still talking about the passing out of this great man, broad of vision and open-hearted, who mixed good deeds with his daily work. His ability as a merchant and manufacturer is unquestioned, but it is the man rather than his business that people are talking about.

Although he only spent a brief period on this earth, his life was a very useful one. He made thousands of other lives brighter and happier, and not only has the world of trade and commerce lost a keen leader, but humble homes have lost a true friend.

As a just and generous employer he was without an equal. His personal knowledge of his employees was amazing, as the following story shows. During the war he discovered in his own quiet fashion that the wife of one of his enlisted employees was contemplating digging up her garden the following day. Bright and early the next morning two men knocked at her door and mentioned in a casual manner that Sir John had sent them up to dig the garden and plant seed for her. A simple story, yes, but it shows the great heart behind the man in the background.

A thousand similar stories could be told for he was always helping someone. Were we allowed to coin a phrase we might say, "He lived—and thousands benefited through his short stay on earth." Would that there were more of his type. Men who could rise to greatest heights, yet always be in a position to stoop and help the less fortunate.

Figures Show An Increase

COMPARED WITH 32,184 tons in January, a total of 33,572 long tons of iron was made in Canada during February, according to official figures from the Dominion Bureau of Statistics. This shows a slight improvement, and the latest total was made up from 25,400 tons of basic iron, and 8,172 tons of foundry iron. Although an increase is shown over the former month we still have a long way to travel before reaching the 1921 average, as the January, 1922, output was the smallest on record for some years back. In fact, February figures, are second lowest, the average monthly tonnage during 1921 being 50,000 tons.

The same can be said regarding Canadian steel production, because although the output of steel ingots and castings in Canada was 9,000 tons higher in February than in the preceding month, it is still lower than the average monthly tonnage during 1921. In February the total tonnage was 42,388 long tons, comprising 40,939 tons of ingots, and 1,449 tons of steel castings. The average monthly output last year was 56,000 tons, or 13,612 tons more than February 1922 production.

Electric steel castings produced during February totalled 772 tons as compared with 856 tons in January, but in the former month practically all castings made were for direct sale.

In spite of these figures showing below the average production of last year, it is a good sign to see this increase over the former month. The steel market in the States is strengthening every week, and prices are now firm in many lines. Canada is bound to feel the effect of this within a short time, so that we can look forward to noting a still further improvement in the tonnage figures for March and April.

That Extra Two Years

ON ANOTHER page of the issue will be found an article on the new Adolescent School Act, this comprising the opinions of several prominent Canadian business men. Although a few disagree with the movement, to keep the youth of Canada in school until the age of 16 has been reached, the consensus of opinion seems to be that the extra two years' study will help, rather than hinder.

It seems to us that a great deal depends upon the nature of the subjects taken up during the critical period, 14 to 16. If the authorities in charge of the various educational institutions are wise, they will see to it that the students receive as much practical education as possible. That is, something which will be of real value to them, after they leave school to earn their living. The average boy cannot afford a college education, and his parents are perhaps anxiously awaiting the time when he can leave school and help earn some money to keep affairs at the home in smooth running order. All men cannot be plant owners or managers, likewise all boys leaving school cannot have the same capability or inclination.

Our suggestion would be this: Let the principals of the various schools study each boy, cultivate his acquaintance, get to know his inclinations; then if he is suited for this work, whether it would be the principal's own choice or not, let him help all he can towards granting the boy his wish. Make his two years additional schooling count for something, so that when the various educational factories, as one might term them, let loose their army of 16 year old business enthusiasts, manufacturers all over the country will feel the extra two years' schooling has been worth while.

Prepare For The Future

BUSINESS may be quiet but that is no reason why manufacturers should not be preparing for better times. When fishermen are not engaged in the catch they are mending their nets and their example might well be followed out by every plant owner during the present lull. This is the time to get together and exchange ideas so that when home and export trade returns we will be able to handle it efficiently.

Several Canadian manufacturers are adopting this building up policy. They are to be especially complimented for their aggressiveness, for when business opens up there is no reason why Canada should not be well to the fore.

A REMARKABLE increase in customs revenue for Toronto is noted in the report for March. The customs and excise revenue will amount to at least $4,500,000 as compared with $3,697,635 for March, 1921. This means at least a total gain of $803,000. The gain over February will amount to over $1,000,000 this being one of the largest on record.

Industrial Activity Showing Upward Trend

Mills Report Good Demand for Structural Steel—Canadian Dealers Secure Machine Tool Orders—Improvements Looked for in Many Lines—Look for Heavy Building Year

MACHINE TOOL ORDERS INDICATE ACTIVITY

A CANADIAN machine tool dealer secured a $30,000 order in American territory a few days ago, in spite of competition from dealers in the States. Some of the tools ordered are not made in Canada, but the Canadian firm receives credit and commission on the business.

Several other good orders in machine tools have been closed, one being for about $10,000 worth of plant equipment. While the tool market is far from booming, conditions are on the upgrade. Enquiries are better, and several good prospects are being nursed along.

Small tools and supplies are selling at a fair rate but the market is spotty, several dealers having off weeks while others report an increase in sales. From the nature of the orders received however, it is plain to see that the stock of the tools in manufacturing plants must be very low, as immediate delivery is the usual cry.

Scrap metals are not moving very rapidly, nor are non-ferrous metals. This applies to all Canadian markets.

Iron and steel is in slightly better demand, but this condition is expected as the season advances. March business shows an improvement of about 10 per cent. over the former month.

Building construction is active, residence building being featured. Montreal predicts a splendid building year. Activity at the different Canadian water fronts is very marked and considerable repair work is proceeding.

The Algoma Steel Corporation is operating at about 60 per cent. capacity, but rail mills in the East are shut down.

Mills report an increased demand for structural steel. Pig iron is in slightly better demand, but nothing like normal.

No one seems to be worrying about the coal strike. Manufacturers are well supplied with coal, and in many cases, stocks are good for three months. One large user, requiring at least a car load every day, reports that he is well supplied, and can run night and day for 90 days. The opinion exists that not only will the miners' wages be reduced, but freight rates as well, thus causing a good sized drop in the price of coal to the consumer.

In the United States, the production of steel has increased considerably during the past two weeks. The present rate of steel ingot production is around 32,000,000 tons a year, compared with 17,000,000 at the end of December. Whether the present rate can be held is another question, as some of the material at present being purchased is going into stock.

The price of bars and shapes in the States is now 1.50c. This brings the level back to where it stood a few months ago. Three or four weeks ago these products could be purchased for 1.35c. Prices all along the line are stiffening, and shading has been practically eliminated.

Plates are quiet, and there is an enormous excess of productive capacity. Several mills stay closed as they do not find it worth while to accumulate enough orders to justify starting. Nails are in heavy demand and the price is firm, $2.40. Hoops and hot rolled strips have advanced $2 a ton during the week and are now 1.90c. Bands are stiffer, and cold rolled strip remains at 3.50c, a price set at the start of the year.

Coal is not much in demand, everybody having stocked up in anticipation of the present strike. Coke has weakened during the past ten days, but pig iron shows a little added stiffness.

Toronto

April 5th.

A CANADIAN firm closed an order in the United States the other day for approximately $30,000 worth of machine tools. This shows conclusively how eagerly business is being followed up at the present time. Some of these machines will be made in the States, but nevertheless the Canadian firm receives the commission. The same company has secured a $10,000 order for plant equipment in Canada, so that they are naturally well pleased with themselves.

From the above information, one must not run away with the idea that the machine tool market has improved overnight. Such is not the case. Conditions are gradually but steadily improving, but the market is still spotty. The two orders previously mentioned are bright spots, but next week it is doubtful, in fact, very improbable, that as much business will be closed by the firm we refer to. Several other dealers report a good week in machine tools. In fact, it seems to have been a rather profitable one for the majority of merchants in this line. What next week will show is another matter. Second hand tools are moving fairly well.

Iron and Steel.—The iron and steel business closed during the last seven days is better. Every week sees a slightly increased demand, which however is but natural, for spring is now with us and building and general construction work is automatically picking up. There is nothing featuring, and prices remain the same. Price shading is practically gone, and several dealers talk about a possible advance at the middle of this month to balance the increase in the States recently on iron and steel bars and shapes. Should this occur, it means bars and shapes would go up to 2.90 the price existing about the beginning of February. Present quotations, however, remain as follows:

Iron bars	2 75
Steel bars	2 75
Reinforcing bars	2 75
Steel hoops	3 75
Tire steel	3 00
Spring steel	6 00
Band steel, No. 10 gauge and 3-16 in. base	3 25
Small shapes	3 00

Pig Iron. — A slight increase in the demand for pig iron is making itself felt. Several foundries report better business, and of course, when this occurs, it means that they will have to order pig, their stocks being so low. The iron and steel market, as well as the pig iron field, are finding this condition true, viz., that users have allowed their stocks to reach the point where immediate delivery is requested. It is safe to say that an increase of at least 10 to 15 per cent. has been made in the demand for pig iron, when comparing March business with February. The price remains firm, $27.15 for No. 1 silicon, 2.25 per cent. to 2.75 per cent.

Non-Ferrous Metals. — Very little change can be reported in this section. The demand is still light, and while a spasmodic spurt occurs for a day or so, it soon settles into the rut again. Prices remain the same, and local quotations are as follows:

Lake Copper	17 00
Electric Copper	17 00
Castings, copper	16 50
Tin	34 00
Spelter	7 25
Lead	6 75
Antimony	8 00
Aluminum	26 00

Small Tools.—This market is becoming very spotty. For example, last week a certain dealer had the best week in six months' time. During the past seven days, the same dealer has not closed enough business to pay expenses. On the other hand, several merchants who reported poor business the previous week are feeling much better when considering the orders closed during the past few days. It would seem as if dealers in this line are getting their good and bad periods, but when the number of sales is totalled up, the volume of business closed during March has improved at least 10 per cent. over February.

Steel Pipe.—The demand for this commodity has increased slightly during the week. Prices are firm, and the companies making this type of pipe are now specifying time deliveries, as they have quite a number of orders on hand. Prices for pipe will be noted on quotation pages.

Miscellaneous.—Waste and wipers continue in good demand. Oils and

greases are selling at a good rate, the automotive trade being partly responsible for the increase. Prices are steady and there is no change recorded. Following are present quotations:

OILS AND COMPOUNDS

Castor oil, per lb.	34½
Royalite, per gal., bulk	21
Palacine	24
Machine oil, per gal.	33 00
Black oil, per gal.	17 50
Cylinder oil, Capital	61 50
Petroleum fuel oil bbls., net	9 90
Pure turp., single bbls. gal.	1 35
Linseed oil, raw, single bbls.	1 00

Castor oil, per lb.	34½
Royalite, per gal., bulk	21
Palacine	24
Machine oil, per gal.	33 00
Black oil, per gal	17 50

Scrap Metals.—Some lines show added activity, but to find a feature is impossible. Buyers are purchasing cautiously, and the margin of profit to dealers is very low. This is a purchasers' market and they are making the most of it. Following are existing prices:

Copper, light per 10 0lbs.	8 00
Copper, crucible	10 50
Copper, heavy	10 50
Copper wire	10 50
No. 1 composition 6...	8 50
New brass cuttings	6 00
Red brass turnings	6 00
Yellow brass turnings	4 75
Light brass	3 50
Medium brass	4 50
Scrap zinc	3 25
Heavy lead	4 00
Tea lead	3 00
Aluminum	10 00
Boiler plate, per gross ton	9 00
Heavy melting steel	10 00
Axles (wrought iron)	16 00
Rails (scrap)	10 00
Malleable	11 00
No. 1 machine cast iron	16 00
Pipe, wrought	6 00
Car wheel	16 00
Steel axes	15 00
Mach. shop turnings	6 00
Stove plate	11 00
Cast boring	5 00

Montreal

April 5th.

AFTER analyzing the reports from various sources regarding the iron and steel business, it is evident that the gradual improvement which has been more or less in evidence for the last few weeks, is still being maintained. There have been no rapid strides in any particular direction, but the general tone is more encouraging. Locally, the activity along the harbor front is daily increasing.

A good amount of machine repair work has been handed out to the various shops, and on the vessels in port, also the floating and land equipment, considerable work is in progress. Building construction is very active, living up to the promises made during the winter. It is predicted that in Montreal and vicinity there will be more building this season than there has been in any season since the boom year of 1913.

Iron and Steel.—The demand for steel is not as heavy as producers would like. The amount of business offering is an improvement, however, over last week, and there is no doubt that the railways will be in the market for steel rails at an early date, and while the looked-for March business did not materialize, it is stated on good authority, that the railways are now making up the figures and that orders will be placed before Easter.

The rail mills in the east are shut down, while the Algoma Steel Corporation is operating at about sixty per cent. of its capacity. Jobbers and the mills report that the demand for structural steel is increasing at a satisfactory rate. No very large orders have been received, but a considerable number of small and medium sized ones. Merchant bars are still moving in a fairly satisfactory manner. Sheets and plates are in good demand, and prices are still firm.

The latest view of the coal strike is that as long as transportation is not affected the supply of steel will be sufficient for all demands. For some months past local mills have been sending their sales representatives to call on the consumer direct. Jobbers have objected to this, especially as price cutting was much in evidence. In fact, many small orders were closed as low as $2.40 base, and in some instances $2.25 base. The base price quoted was $2.75, so it can be seen how keen the competition became. There is every reason to believe that jobbers and the mills are now getting together and will maintain quotations. Prevailing prices quoted are:

Iron bars	2 75
Steel bars	2 75
Reinforcing bars	2 75
Steel hoops	3 75
Tire steel	3 00
Spring steel	6 00
Band steel, No. 10 gauge and 3-16 in. base	3 25
Small shapes	3 00

Pig Iron.—Very little has happened in the pig iron market during the week. No changes in quotations have been made. Local dealers have been keeping their eyes on Buffalo, as this market has a definite influence on local quotations. It has been ascertained that Buffalo furnaces have taken a good deal of business in New Engand territory, and this material will be delivered via the new Barge Canal. Most of these orders are for eighteen dollar iron, and as it is well known that every ton of such iron represents a loss, it is stated that quotations will immediately be revised upward. If such is the case it will ease up the situation locally for iron is at present being quoted at $29.80 for No. 1 iron.

Machine Tools and Supplies. — Although contract plants have been more active lately than since last autumn, they find that their present machine tool equipment is sufficient to take care of all requirements. For that reason they cannot be interested in new machine tools. Railway shops and the large plants operating machine shops are not interested in anything in a big way in machine tools, the result being that sales are not much in evidence. Occasionally single tools are sold, and salesmen are very aggressive, price shading being often in evidence. Inquiries are fairly numerous, but it is difficult to turn inquiries into business. The supply end still continues to be good, and a gradual increase from week to week has been noticed. An off week is reported occasionally, but the general feeling is one of improvement. Prices on supplies are steady, the only flurry being an occasional further discount from list.

Non-Ferrous Metals.—No changes in local quotations on non-ferrous metals are reported, and business appears to be merely dragging along. The market has been featureless for some time past, and it was thought that the large order received by the Northern Electric Co., about ten days ago, would have thrown them into the market for metals, but dealers have been disappointed in this connection. In the list of local quotations it will be noted that prices are as low as they were last summer at the lowest period of the depression. Local quotations are:

Lake Copper	16 75
Electric Copper	16 50
Castings, Copper	16 25
Tin	34 00
Spelter	7 00
Lead	6 50
Antimony	6 50
Aluminum	23 00

Scrap Metals.—Scrap metals show a slightly better demand, but local conditions are still weak. There appears to be ample material to supply all the light demands. Quotations locally are as follows:

Copper, light per 100 lbs.	8 00
Copper, crucible	10 50
Copper, heavy	10 50
Copper wire	10 50
No. 1 composition	8 50
New brass cuttings	6 00
Red brass turnings	6 00
Yellow brass turnings	4 75
Light brass	3 50
Medium brass	4 50
Scrap zinc	3 25
Heavy lead	4 00
Tea lead	3 00
Aluminum	10 00
Boiler plate, per gross ton	9 00
Heavy melting steel	9 00
Axles (wrought iron)	17 00
Rails (scrap)	10 00
Malleable	10 00
No. 1 machine cast iron	18 00
Pipe, wrought	7 00
Car wheel	18 00
Steel axes	16 00
Mach. shop turnings	4 00
Stove plate	16 00
Cast boring	3 00

Pittsburg

April 5th.

PRODUCTION of steel has undergone a noticeable increase in the past week or two, after having been practically stationary for two or three weeks. The rate of steel ingot production at present may be estimated at 31,000,000 to 32,000,000 tons a year, against 29,000,000 tons at the end of February, say 17,000,000 tons at the end of December,

and 23,000,000 tons in October and November

Except for the inconsequential exception that a few pipe mills are stocking pipe to a limited extent, all the production of steel is based on actual shipping orders, so that production is a correct and prompt reflection of the orders received by mills. The only question as to the entire soundness of the steel situation is in connection with the possibility that buyers have lately been stocking to such an extent that in future they will not require as heavy shipments as they are receiving at the present time.

Iron and Steel Production. — That there has been some stocking is beyond doubt. Many of the orders have shown that buyers were rounding out stocks, while there is independent confirmation of the point in that anyone can observe that steel is not being actually consumed at the rate at which it is being produced and shipped. The present rate of production is in excess of the average rate in 1912 and 1913, the two best tonnage years before the war, with about 30,000,000 tons of ingots made in each year, yet it is plain that there is not the same degree of general industrial activity now as in those years. There is more dwelling house construction and more production of automobiles, but there is not nearly as much production of factories, bridges and skyscrapers, and not nearly as much railroad steel is being taken.

The situation would be clearer were it not for the coal strike that began April 1. The stocking of buyers would be attributed to their having allowed stocks to go down to an unreasonably low level and to their knowing that they would have need of more steel in spring. Presumably buyers know what they need and what they do not need. They would not buy for fear of demand outrunning productive capacity, for the production of steel in the past three months has been just one-half of steel-making capacity, so that the buyers have had a 100 per cent. margin of safety. They could have doubled their orders and merely filled the mills.

The coal strike, however, makes a difference. Buyers may have feared that it would interfere with production and shipments, and they may have ordered extra steel before April 1 against the possibility that the coal strike would prevent their getting desired deliveries after the strike had been going a few weeks. If that has been the case there is a possibility of orders beginning to fall off shortly. Thus far there is no evidence, in the actual market, of anything of this sort.

Prices Stiffening.—Mills have been very keen to secure higher prices when at all possible, much keener to stiffen prices than they were in the first place to try to keep them from going down. The market in bars and shapes has gradually worked upward until now it is fairly quotable at 1.50c, against 1.40c a week ago, and 1.35c three or four weeks ago. The 1.50c price is not absolutely maintained on all business, but concessions have obtained only in the case of particularly desirable orders. Some mills have passed up orders rather than shade 1.50c. Again, some small orders have been going at 1.55c and 1.60c, particularly when the specifications were undesirable. To illustrate, a carload of bars in two sizes would probably go at 1.50c and a carload in a dozen sizes at 1.60c.

It is a question where plates should be quoted. They are not active and there is an enormous excess of productive capacity, but the price has some stiffness because some mills simply stay closed, not finding it worth while to try to accumulate enough business to justify starting, while some producers who make bars and shapes also hold plates at the same price as bars and shapes whether they get plate orders or not.

Nails are very firm at $2.40 and the market is in strong position, with a decidedly heavy demand. Mills would probably succeed if they tried to advance to $2.50 but they are disposed to let well enough alone.

Heavy Sheet Bookings.—Placing of actual orders for sheets, and contracting for second quarter delivery has been heavy in the past week or two, since mills began announcing that their prices would be advanced $3 a ton April 1, or close to that date. If the threat of an advance was made, as is asserted in some quarters, because certain mills were running out of orders the move has been quite successful, and by the time the business is all summed up it will probably be found that buyers generally are well covered to July 1, at prices lately ruling, 2.25c for blue annealed, 3.00c for black, 4.00c for galvanized and 4.35c for automobile sheets. The covering in blue annealed has not been as extensive as in black and galvanized, since it has been quite uncertain whether blue annealed would really go up, and there has also been some conservatism on the part of the automobile trade. The American Sheet and Tin Plate Co., issued no notice to the trade that it would advance its prices, but its customers evidently assumed that it would make an advance if the independents did, for they have been buying quite freely.

Hoops and hot rolled strips have advanced $2 a ton in the past week, being now quite steady at 1.90c, the prise at which cut hoops have been for several weeks past. Bands are stiffer. Cold rolled strip remains at 3.50c, where it has been since January 1, and is unlikely to change in sympathy with the advance in hot rolled strips.

Never in the case of the numerous "suspensions" the bituminous coal mining industry has had was a suspension so widely expected or so long in advance, as the one that began April 1, and naturally buyers stocked up accordingly, being so anxious to be forehanded that they ceased being very active buyers about the first week in March, since when the coal market has been dull with prices declining. On the day the strike began, non-union producers marked their prices back to where they had stood before the March decline began, but there has not been enough trading to show where the market stands, there being hardly more than asking prices. Evidently the steel producers are satisfied that they will get along all right. With assistance from the non-union fields, even allowing for considerable labor trouble at non-union mines, the steel mills are probably assured of a supply much longer ahead than they have orders for steel.

Connellsville coke has weakened slightly in the past ten days, but is still as high as early in February after prices had recovered from the low level obtaining in the fore part of January, when spot furnace was $2.75 to $3.00, against $3.25 to $3.50 at present. As demand for coal began to decrease about March 1, Connellsville operators began blowing in more coke ovens, and from time to time it appeared there would be a surplus of coke, but each time demand seems to have increased enough to prevent any serious slack developing. Foundry coke remains at $4.25 to $4.75, depending on brand, with a slightly better selection of brands at $4.25 and $4.50.

Pig iron is even firmer than a week or two ago at $19.50 for Bessemer, $18 for basic and $19 for foundry, f.o.b. valley furnaces.

LOWER CUSTOMS RATE ON AUSTRALIAN IMPORTS

A report from the Canadian Trade Commissioner's office in Melbourne, Australia, shows a list of materials and articles which may be imported into Australia at reduced rates of duty if used in the manufacture of specified goods, or for specified purposes. Among those mentioned are certain sizes of iron and steel sheets; drill chucks and four-jaw independent chucks; machines for the manufacture of wheels for children's tricycles and accessory equipment; wood and metal patterns for use in the manufacture of alternating current electric motors, (this line is limited to one set of patterns for each motor frame size for any one importer or manufacturing firm); tractors, caterpillar and cable plowing types. Other appliances include irons for planes, shears, winding pulleys, etc. The above specified minor articles, machine tools and parts, and tools of trade, are now admitted (for the purpose specified) free of duty if from the United Kingdom and at the rate of 10 per cent. ad valorem if from any other country.

MANY NEW VESSELS USE DIESEL DRIVE

The efficiency of the Diesel engine is rapidly proving its superiority in marine practice, so much so that large ocean transport companies are adopting this type of power in many of the new vessels under construction, and likewise fitting out existing vessels with the Diesel engine when conversion is decided on.

SELECTED MARKET QUOTATIONS

Being a record of prices current on raw and finished material entering into the manufacture of mechanical and general engineering products.

PIG IRON

Toronto price:—	
Silicon, 2.25% to 2.75%	27 15
Grey forge, Pittsburgh	$19 00
Lake Superior, charcoal, Chicago	30 00
Standard low phos., Philadelphia	41 50
Bessemer, Pittsburgh	19 50
Basic, Valley furnace	18 00

IRON AND STEEL

Per 100 lbs. to Large Buyers	Cents
Iron bars, base, Toronto	$2 75
Steel bars, base, Toronto	2 75
Iron bars, base, Montreal	2 75
Steel bars, base, Montreal	2 75
Reinforcing bars, base	2 75
Steel hoops	3 75
Tire steel	3 00
Spring steel	6 00
Band steel, No. 10 gauge and 3-16 in. base	3 25
Chequered floor plate 3-16 and heavier	6 00
Bessemer rails, heavy, at mill	2 35

News From the Industrial Field

Plans have been prepared for the new Eastwood School, Edmonton, Alta., estimated cost $465,000.

Erection of a factory costing $30,000 is contemplated by the Crystalline Milling Co., 120 Bay St., Toronto.

The Canadian Wire Bond Boxes Ltd., 17 Mill St., Montreal, Que., is in the market for a 40 h. p. electric motor.

The Manitoba Rolling Co., Winnipeg, is in the market for a 36 in. lifting magnet for handling scrap; also 100,000 lbs.

Erection of addition to factory, three storeys, is contemplated by the Durant Motors of Canada, Ltd., at Leaside, Ont.

A. H. McPhail, architect, is preparing plans for a newspaper plant to cost $200,000 for the Border Cities Star, 104 Sandwich St., Windsor, Ont.

The proposed technical and vocational school for St. Thomas, Ont., now has the unanimous backing of the financial committee of the city council.

The Provincial Government plans construction of a dam on the Chaudiere River near St. Georges, Que., to develop 2,000 h. p., cost to be about $800,000.

A permit has been issued for the erection of a new Windsor and Walkerville technical school on Giles Blvd. and Elsmore Ave., Windsor, Ont., to cost $689,000.

A large addition to cost about $150,000 will be added to the University of Ottawa building, this year. Plans have been completed and work will likely start within a month.

Erection of a protestant orphan children's home costing between $200,000 and $250,000 is projected by the directors of the St. John Protestant Orphans' home, St. Johns, N. B.

Contracts for three large pressure filter tanks required for the Howard Smith Paper Mills Ltd., is awarded to Walsh Plate and Structural Works of Drummondville, Que.

The numerous brick plants at Milton, Ont., are said to be engaging large numbers of new men and have adopted a ten-hour day in anticipation of a busy season in construction work.

The St. Lawrence Balling Co., 23 St. Francois Xavier St., Montreal, is in the market for three electric motors, one ton and a half h.p., one three and a half h. p. and one two h. p.

The Board of Education, Guelph, Ont., will soon receive bids for a three storey collegiate including a vacuum steam with mechanical ventilation systems. Cost to be about $320,000.

Erection of a factory at the cost of $80,000 is contemplated by the Western Clock Co., 383 George St., South Peterboro, Ont. John H. Vernor of the same address is the party interested.

The city of Sault Ste. Marie, Ont., is having plans prepared for the installation of two gasoline engines for direct connection to present pumps in the pumping station. Cost to be about $20,000.

The Standard Steel Construction Co., of Welland, Ont., have secured the contract for all the construction steel work of the new warehouse building for the Canadian Ramapo Iron Wroks at Stamford, Ont.

A by-law will be introduced at the next meeting of the city council of Toronto, providing for the arranging of $109,000 for the erection and equipment of a technical school on Greenwood Avenue.

The Board of Education of Carleton Place, Ont., is asking the town council to submit a by-law for $110,000 in order to erect a new high school building and convert former premises into a public school.

A deputation from the County Council of Chatham, Ont., recently appeared before the Minister of Public Works, Ottawa, to ask for a $10,000 grant towards the construction of a bridge over the river at Prairie Siding.

The Toronto Transportation Commission will build a machine shop in Hillcrest Park at an estimated cost of $100,000. Equipment has not been purchased. It is also receiving bids for 8,000 tons of steel rails.

The Hamilton plant of the Canadian Libby-Owen Sheet Glass Co., Hamilton, commenced operation early this year. It is now producing at full capacity, and orders on hand warrant such operations being maintained for the balance of the year. This plant is operated continuously day and night.

Sir Adam Beck, Mayor Maguire of the city of Toronto, and the local Hydro commission met recently to discuss this year's program of capital expenditures by city Hydro system, which calls for $2,500,000. The chief subject of consideration was the new Hydro head office building at the corner of Front and Yonge St.

The plant of Walthausen Hat Corp. at Brockville, Ont., has been working at full capacity for the last twelve months, and the company has been unable to accept all export business offered. An officer of the company states that a 100 per cent. addition to plant is desirable when money conditions are easier.

Orders for ten marine boilers were received recently by the Engineering and Machine Works of Canada, St. Catharines, Ont., and the boiler department will be kept busy during the spring weeks, with both night and day shifts employed. Eight of the boilers are for delivery at Three Rivers, Que., and two are for Collingwood, Ont.

At a large meeting held recently at Renfrew, Ont., it was unanimously decided to proceed at once with the building of the new collegiate institute. Each of the members on the board of education addressed the meeting briefly, and also several of the large taxpayers voiced their approval. It was proposed to have the old collegiate building taken down before May 1st, 1922.

At a recent meeting the board of education of Oshawa, Ont., decided to spend $220,000 during the coming summer on the schools of Oshawa. The board decided that instead of spending $200,000 on the erection of one sixteen roomed school on the site now occupied by the Tennis Street school, they would build a twelve-roomed school on this site and an eight-roomed school in the south-east section of the city.

Last fall, piling was placed for the foundation of an addition to the north-western elevator, situated on the upper reach of the Kaministiquia river at Fort William. Work on the superstructure is now under way and will be carried on continuously until completion; this will be in time to participate in the handling of the 1922 crop. The additional storage space beng provided is 2,500,000 bushels. Construction is of reinforced concrete. The cost will be approximately $500,000. Barnett and McQueen are the contractors.

About as good a method as any of ascertaining how business is picking up, is to watch the volume of freight and general merchandise passing through the railroad yards. From official figures received, we find that freight business has increased about 15 per cent. since the start of the year, while smaller packages have increased in volume about 18 per cent. This shows conclusively that improvement is occurring, and the variety of products handled is exceptionally large. The percentages given are not confined to a few localities, but are an average of over 30 principal points throughout Canada.

The Canadian General Electric Co., has closed a good order from the west. Speaking to Canadian Machinery about this matter, Mr. Ashwoth, of the Toronto office, said that the order has been secured from the Manitoba Power Co., and includes the following equipment: Two, 21,000 k.v.a. water wheel driven vertical generators, and six, 7,000 k.v.a., 11,000 to 60,000 volts core pipe transformers. These are to be erected at the

Manitoba Power Co. plant at Great Falls which is adjacent to the present power plant of the Winnipeg Electric Railway Co., at Vac Bu Vonnet. Eventually the capacity will consist of 6 of these machines, in other words, three times the equipment now being provided.

Highway Crossings Ltd., manufacturers of steel crossings for use at railway intersections, have decided to locate their Canadian plant in Welland, Ont. A site for the factory has been secured in the Maple Leaf Park. The company's product is designed to take the place of wooden planks at highway crossings. A test is being made at the present time for the Canadian National Railways to show the advantages claimed for the steel crossings.

The Textile Industries in Canada showed a continued improvement during the month of February, according to reports received by the department of labor. Employment in the cotton mills in various towns reported a minor increase in activity, while the hosiery and knitted goods factories registered the same staffs as during the preceding months. In Quebec the situation is considerably more favorable than it was in January, improvements being reported in practically all branches of the industry.

For some years past the corporation by the name of Lachine Rapids Power Co., has been gathering data and preparing to finance a plant for the erection of a gigantic dam below the rapids to Heron Island in the St. Lawrence River, but the outbreak of the war prevented the action. It is rumored that efforts to put the scheme on its feet, through re-organization and strengthening of the concern, are to be made shortly. It is said that the work itself would cost in the neighborhood of $175,000,000.

The effort of the Canadian Department of Trade and Commerce to secure the establishment of branch plants of British firms for this country will be directed in London, England, by Trade Commissioner L. D. Wilgress. The department is desirous that boards of trade, chambers of commerce and industrial commissioners throughout the dominion shall communicate with Mr. Wilgress, giving him publications, statistics and other specific information regarding industrial openings in their own localities. An important part of the data placed in the commissioner's hands will relate to transportation facilities, raw material, labor, power cost, taxation, etc. Mr. Wilgress will get in touch with British manufacturers with a view to interesting them in the location of branch plants, and his work will be all the more effective if he receives the co-operation of organizations that have the same end in view.

Preparations are now under way at the Ontario Reformatory for the opening of a cannery which will be the largest in operation at any government institution in Ontario. It is expected that between 40,000 and 60,000 gallons of canned goods will be turned out this year. A large amount of new machinery for the canning factory has arrived and the balance is expected very shortly, and as soon as the coming season opens the inmates will have the new industry in full operation. Small canning plants are now being operated at the government institutions in London, Whitby and Hamilton.

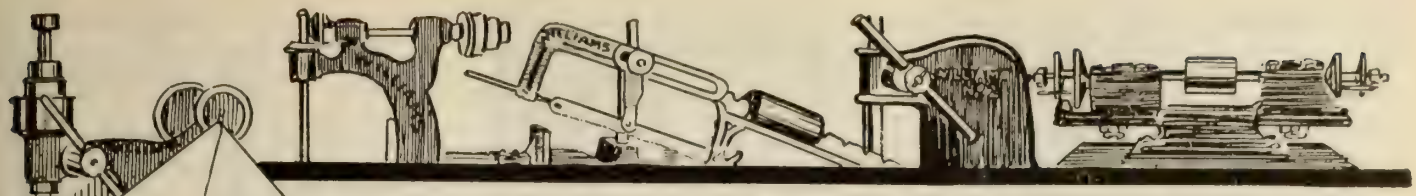
C. A. Stirling, assistant manager of the Robbins & Myers Co. of Canada, Brantford, Ont., tells Canadian Machinery that they are finding a better feeling throughout the country. Enquiries are coming in faster, developing into orders in many cases.

Plans for hurrying up a start on the construction of the new east-end technical school, Toronto, were under discussion at a meeting held recently. It was announced that some final re-adjustment of the financial arrangement between the city and the province had still to be made, and that the matter would be voted upon at the meeting of the city council within the next few days. As soon as this last obstacle has been overcome the advisory committee of the school board plans to call a special meeting to give final approval to plans and to arrange for the speedy calling of tenders.

In connection with the passing of the bills of the Montreal Service Corporation and Canadian Light and Power Co., by the Quebec legislature, the statement is made at Montreal, Que., that the completed merger of these power interests will result in a capitalization of approximately $100,000,000. With the powers now granted, the development of the Ottawa at Carillon will be proceeded with as soon as weather conditions will permit, a considerable portion of preliminary work having been already accomplished. It is further claimed that the consolidation will finally result in the production of upwards of 300,000 h.p. much of which has already been contracted for. To carry out the work to completion the total of $40,000,000 will be required, it is claimed, all of which will be expended during the next two years. The financial plans are well advanced.

The Enterprise Foundry Co., Sackville, N. B., have completed a new steel shop for making bodies for steel and gas ranges, and the wing for japanning. A number of sheet metal working machines have been installed in the addition and those in the main plant have been moved in. By these improvements the output of this department will be considerably increased. As the plant covers so much ground that power can be no longer advantageously transmitted by shafting, part of it is being electrified. Another new development is the installation of a large air compressor which can be used for sand blasting and other foundry work.

A new industry has been secured for Oshawa, Ontario. It has been announced from reliable authority, that W. E. Phillips, Limited, a recently organized company, has secured an option of the plant of the Thornton Rubber Co., in this city which a few weeks ago was destroyed by fire. It is understood that as soon as the necessary transfer papers are filed the new organization will commence re-building the plant and equipping it with new machinery for the manufacture of wood-work, moulding, mirrors, picture frames, etc. It is the intention of the company to have the plant in shape for active operation by May 1st. At first 50 men will be employed but ultimately it is expected the plant will require some 150 to 200 men.



A report from Saskatoon, Sask., states that as a result of the introduction of a one-man car on the Saskatoon street railway system a deficit of $8,996 as compared with a deficit of $58,884 for 1920 is shown by the year 1921, a reduction of approximately $50,000. It certainly speaks well for the new cars.

Here is what Mr. S. L. Squire, chairman of the executive committee, Canadian Good Roads Association, has to say on the automotive question in Canada. Twenty years ago there were less than 300 cars in Canada or one car for each 1,360 miles of road; we now have one car for every mile of improved road. It is clear that for motor use, the road is 1,300 times as important as it was 20 years ago.

Timber as well as water power to ensure an unlimited supply of newsprint paper exists in Newfoundland, according to Wm. S. Coaker, Minister of Marine in Newfoundland, who is at present in New York city. Mr. Coaker stated that in addition to the paper pulp mills the capacity of 400 tons a day which was being promoted by British interests, there was sufficient wood and water power in the Humber River area to permit the establishment of mills to turn out another 600 tons a day.

The pulp and paper industry is lightly regarded as one of the most important of Canadian manufacturing industries, this being strikingly demonstrated by the figures for its operation during 1920, just issued by the Dominion Bureau of Statistics. The total capital invested is given at $347,553,358, of which $221,472,538 is in pulp and paper mills, $103,659,445, in pulp mills and $22,421,352 in exclusively paper mills. This, it may be added, was considerably increased during the early months of 1921. The total number of all mills is returned at 100, Quebec leading with 46, Ontario next with 37. Quebec has the largest number of pulp mills, 18; Ontario comes second with 7.

An increase in manufacturing space from 2,000 sq. ft. to 50,000 sq. ft. is the record of development of the Brantford Computing Scales, Ltd., of Brantford, Ont. This new plant, already completed and fully equipped is said to be the largest and finest of its kind in the British Empire, and is capable of handling a turnover of approximately $2,000,000 a year. Until two years ago, the company did its business exclusively in Canada but latterly repeat orders have been received on shipments made to Great Britain, the United States, Australia and New Zealand.

"WILLIAMS"

Re-Manufactured Machine Tools

You can save a lot of money buying our used machine tools, because you get machines that have been thoroughly remanufactured and trued-up—machines that are guaranteed absolutely as good as new, much below new prices.

Why pay the full price for a new tool when a much smaller investment will give you equally satisfactory results?

Our name and reputation constitute a guarantee that any machine you buy will be exactly as represented.

If you are interested in receiving our monthly Machinery List, write us and we will put your name on the mailing list.

THE BURKE MACHINE TOOL CO.

520 Sandusky St., Conneaut, Ohio, U.S.A.

Canadian Dealers:—H. W. Petrie, Ltd., National Machinery & Supply Co., A. R. Williams Machinery and Supply Co., Canadian Fairbanks-Morse Co., Williams & Wilson, Garlock-Walker Machinery Co., Yeates Machinery Co., Cope & Sons.

The ratepayers of Mount Elgin, Dereham Township, have decided to go ahead with the construction of a continuation school, at an estimated cost of $15,000.

Fire of unknown origin broke out on March 20 in the sawmill of the Kastner Lumber Co., Wiarton, Ont., destroying the mill, with a loss of between $5,000 and $6,000.

The Paris Knitting Co., Burford, Ont., has secured an old factory building and plan to install equipment for the manufacture of socks and stockings; estimated cost $30,000.

The production of brooms and brushes in Canada during 1920 was valued at $4,680,985, compared with $4,284,915 in 1919. In 1920 there were 55 plants engaged in making these products with a capital investment of $3,780,252. Exports to the United States decreased from 1919, but the value of goods sent to the United Kingdom and the British possessions increased.

The starch and glucose industry of Canada produced goods to the value of $8,379,185 during 1920, according to a report issued by the Dominion Bureau of Statistics. Comparing these figures with the total for 1919 shows an increase of over $500,000. The capital investment for 1920 was $6,112,124. Three Ontario plants represented practically the whole Canadian industry since only 10 people were employed in the two plants located in Quebec and Prince Edward Island.

For some time reports have been in circulation that the Canadian Locomotive works, Kingston, Ont., which have been closed since May last, are to reopen in April, but at the office of the works nothing definite is known. It is known that orders have been offered to the company, but that it would not pay to reopen the plant unless enough work was secured to keep the place busy for a year at least. As the locomotive works is Kingston's biggest industry, employing between 700 and 800 men, news of a large locomotive order is eagerly awaited.

The following are some very interesting figures showing the standing of the individual provinces for the Dominion of Canada with regards to automobile ownership.

Province	Cars	Population	Persone p.c.
British Columbia	90,600	31,000	16
Saskatchewan	45,010	62,958	12
Alberta	81,995	38,750	15
Manitoba	15,008	40,430	15
Ontario	2,929,054	206,900	14
Quebec	2,349,067	59,707	39
P. E. Island	88,538	13,051	50
New Brunswick	88,092	13,584	28
Nova Scotia	24,579	14,250	36

In all, this is a total of 569,000 motor vehicles which shows an average for the Dominion of one car for each 18 persons, or one car to every three families.

Commenting on the proposed development of the St. Lawrence deep water project, Col. Gear of the Montreal Shipping Federation, stated that if the scheme were carried out, it would result in incalculable damage to Canadian shipping and likewise delay in navigation through holding back the flow of the ice each spring. He instanced the cost as another objection, and intimated that the power development would benefit the United States more than Canada. He urged that the government study the report of the Shipping Federation, made to the International Waterways Commission.

MANY LINES GIVE PROMISE OF IMPROVEMENT

Discussing the building and general business outlook in the United States, the National Bank of Commerce says that the present activity in building operations is an outstanding feature. The building industry is second in importance only to agriculture, and in the more active building sections of the country that are systematically reported, comprising about half the states, considerably more than two billion dollars in contracts were awarded last year.

High freight rates due to labor conditions and high wages to labor are the controlling factors in building costs. They maintain construction prices at levels that interfere with the full and well-rounded development of building operations. They also serve to inject an element of fixed inflation into this, the greatest construction movement in the nation's history.

The lack of well-balanced development is made manifest by an analysis of contracts let and permits issued to date. Residence construction leads. Public buildings, roads, bridges, and other types of building for public purposes are next in importance, stimulated somewhat by desire to relieve unemployment. Business and industrial construction, which must be done on a basis of cost that will permit a present and continuing return on the investment, has not expanded correspondingly.

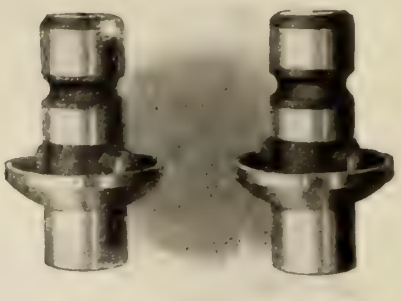
Despite the handicap of high costs, home building activity is being maintained for the present because the housing necessity compels it, even on the basis of uneconomical investments. Public building and construction are also being done on a high cost basis which will be reflected in high tax rates for years to come. Public building, like residence building, cannot continue indefinitely under these conditions.

Labor itself is the chief sufferer in the situation. Resistance by important classes of labor to wage declines in a period of declining prices disorganizes the entire productive organization of the country and contributes to unemployment in other lines. The maintenance of building operations on high wage levels delays general wage readjustment. It means exorbitant rents and prohibitive costs for homes for workmen. It is a general deterrent to a return to normal industrial, commercial and financial activity.

On the whole labor costs in the building field are not greatly reduced from their maximum. Transportation is a very large part of the laid-down cost of building materials and the adjustment of railroad rates is deferred by the refusal of railway labor to recognize that the period of war wages is over. In other words, high building costs are being maintained directly and indirectly by labor costs. It is there that the fundamental correction must be made.

Improvement in business with increased stability in underlying conditions characterized the period from February 16 to March 15. Prices of the major commodities have shown only normal fluctuations. Many lines of industry give evidence of increased activity and there appears to have been some decrease in industrial unemployment. Retail trade over the counter is reported as unsatisfactory, but mail order houses generally show an increase in business, attributable to the improved purchasing power and mental attitude of the farmer, due to the rise in agricultural prices.

Wholesale trade is generally reported to be better, although a considerable degree of caution wisely prevails. The rate of iron and steel production has increased, but the volume of forward orders still remains restricted. Immediate demand for boots and shoes is less active and other sections of the hide and leather trade continue to lag. The cotton textile situation is handicapped by strikes in the New England cotton mills. Wool manufacture is operating at a fair rate, although the demand for woolen and worsted fabrics has been disappointing. There has been a marked increase of activity in the manufacture of automobiles, tires and accessories. Car loadings have increased materially during recent weeks. Exports are at a low level, but this is normally the season of a light export movement. Business failures have declined in number since the beginning of the year. The past month has shown improvement in fundamental conditions, and consequently in business sentiment, as has been the case each month since midsummer of 1921.



HANDSOME VOLUME

Hendey 1870-1920 is the unassuming title of an excellently arranged book issued by the Hendey Machine Co., Torrington, Conn., and which covers in a brief, yet thorough manner the founding and activities of their company. The edition of this book is limited to friends at home and abroad, and anyone reading it cannot help but feel that considerable thought has been given in its preparation.

Starting with a story of the founder, Henry John Hendey, the forming of the partnership is described, the first and second shops occupied being illustrated. Then comes a description of the forming of the stock company, followed by other exceedingly interesting chapters. The latter portion of book shows the photographs of the various presidents, and all officials are listed on another page. Several remarkably clear photographs of the present plant interior are shown throughout the book.

Make a Turret Lathe of Your Engine Lathe

Jarvis Collets convert an engine lathe into a turret lathe by simply using one of the Jarvis Quick Change Chucks, which allows the use of any number of different tools.

Acquaint yourself now with Jarvis High Speed Tapping Devices and Quick Change Chucks and Collets.

The booklet will be a worthy addition to your Mechanical Library.

It is interesting—

It is free—

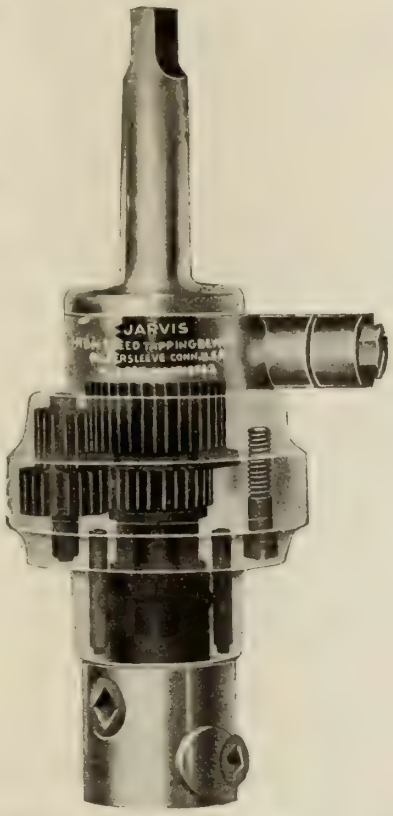
It is yours for the asking—

The Jarvis High Speed Tapping Device is superior to any other.

It has a ball drive and ball reverse, making easiest action, with no clinching or binding.

Reverse motion faster than the drive.

Specially designed Chucks make special taps unnecessary.



Tap breakage reduced to the minimum.

It makes no difference whether the tap is forced against the work in a Drilling Machine, or the piece is pushed towards the tap in a Speed Lathe.

Two Styles of Chucks.

Seven Sizes of Tappers.

Range of Tapping from 0 to 2 inches inclusive.

Jarvis Tappers and Quick Change Chucks

And collets are developed to such a degree of perfection that the Geometric Tool Company recommends and furnishes them as a fitting adjunct to their line of threading tools.

Where one hole is drilled, reamed, counterbored, tapped and a stud set, or any two of these operations are done with one spindle, the Jarvis Quick Change Chucks pay for themselves in a very short time. Changes are made without stopping the Drilling Machine or Lathe.

There is no burring from constant use to interfere with the easy entrance or operation of the Collet.

Jarvis Quick Change Chucks and Collets consist of a chuck or locking member and a sufficient assortment of collets for any job.

Any standard Drill Chuck can be fitted to the Morse Taper Collets.

Combination Tapping Device and Quick Change Chuck

In place of the regular chuck, the Tapping Device is equipped with a Quick Change Chuck, forming a Combination Tapping Device and Quick Change Chuck. This is the combination much in demand.

The Booklet tells the Complete Story. *Write Now.*

ACCIDENT REDUCTION FREELY DISCUSSED AT CONVENTION

THE JOINT Safety Convention under the auspices of the Canadian Manufacturers' Association Board, Department of Labor, Ontario Safety League, Ontario Pulp and Paper Makers' Safety Association, Electrical Employers' Associatioff, Lumbermen's Safety Association and Industrial Accident Prevention Associations, got off to a good start on April 4th at the King Edward Hotel, Toronto. Several papers were presented of importance, and at a later date Canadian Machinery will treat these in more detail.

The first paper was given by Mr. S. Price, chairman of the Workmen's Compensation Board and he dwelt in detail upon Ontario's Accident Prevention Policy. He gave some interesting figures which showed the work his board was doing, and brougt out some very vital facts.

The next paper was presented by Miss Muriel Mackay, chairman of the subcommittee on Industrial Nursing of the public health section, Canadian National Association of Trained Nurses. In a very able manner she brought out the importance and necessity of nurses in industrial plants.

The third paper by Dr. C. L. Starr, professor of surgery, University of Toronto, was entitled "Surgical Treatment of Accident Cases," and Dr. Starr proved conclusively that only the highest quality surgeons should be engaged in this work. He pointed out that a surgeon engaged in industrial accident treatment should endeavor, whenever possible, to save a member of the body, but on the other hand, where he felt that the recovery of the member was extremely doubtful, he should insist on an operation, remove the member, and get the worker back as soon as possible. He also mentioned that although a workman might not perhaps be able to perform his usual task, he could start on lighter work until his injured member was functioning properly.

The last paper by S. J. Dickson, chief constable for Toronto, was on the subject of "Traffic Accidents," and he brought out in a very able manner the causes of the numerous accidents occuring in any large city. He emphasized the importance of checking up the capability of the driver of any automotive vehicle, and suggested that some law be enforced which would necessitate every driver going through an examination.

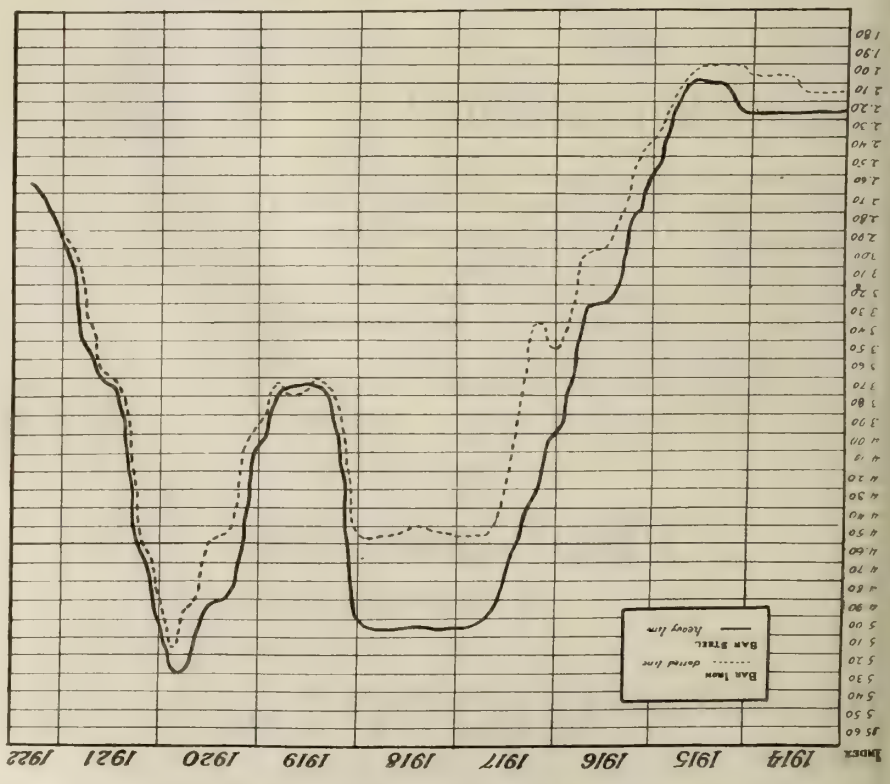
Leslie Hall, of the Williams Tool Corp., Brantford, Ont., and Erie, Pa., was a visitor in the office of F. F. Barber Machinery Co., Toronto, and stated that on his recent trip, lasting four weeks, through the States, that conditions in the machine tool business were showing exceptional activity all along the line.

PLANTS ARE WELL SUPPLIED WITH COAL

ALTHOUGH the coal miners are now on strike, there is no need for worry so far as Toronto manufacturing plants are concerned. Canadian Machinery got in touch with a large number of factories, covering a wide range of activities, and with very few exceptions, they are stocked up with coal for about three months or more and are paying little attention to the strike. Some firms are prepared to keep going until July 1st, without difficultiy, these being large users who consume about 15,000 tons a year.

The consensus of opinion is that there will be no difficulty in securing coal, even if the miners decide to stay out for some considerable time, for the government will no doubt have stepped into the breech before three months have passed.

The only real danger would be with the railwaymen. If they went on strike it would tie up traffic, but as the men on the railroads are well satisfied, there is little likelihood of this occurring. As one large coal dealer put it, "The day of sympathetic strikes is about over, and if consumers will just sit tight, refuse to worry and not rush into a panic buying movement, the complete matter will soon be settled."



CONDITIONS HAVE IMPROVED IN MANY QUARTERS

(Continued from Page 50)

going on at the Border Cities. To believe what has happened here within the past few years, our Eastern friends would require to see for themselves —and even then, they are wonderful almost beyond belief. Miles upon miles of absolutely new streets, lined with fine homes, have come into existence within the lifetime of a little child not nearly old enough for kindergarten. No development that I ever witnessed in Saskatoon, or other Western city, during the boom of 1910-12, eclipses what I have witnessed right here at this most southern extremity of Canada. It will not be very long until one of Canada's great cities will be located right here. At the present time we are the third largest industrial producer in Ontario, and the recent census gives us a population increase of over 138 per cent.,— the greatest in the Dominion.

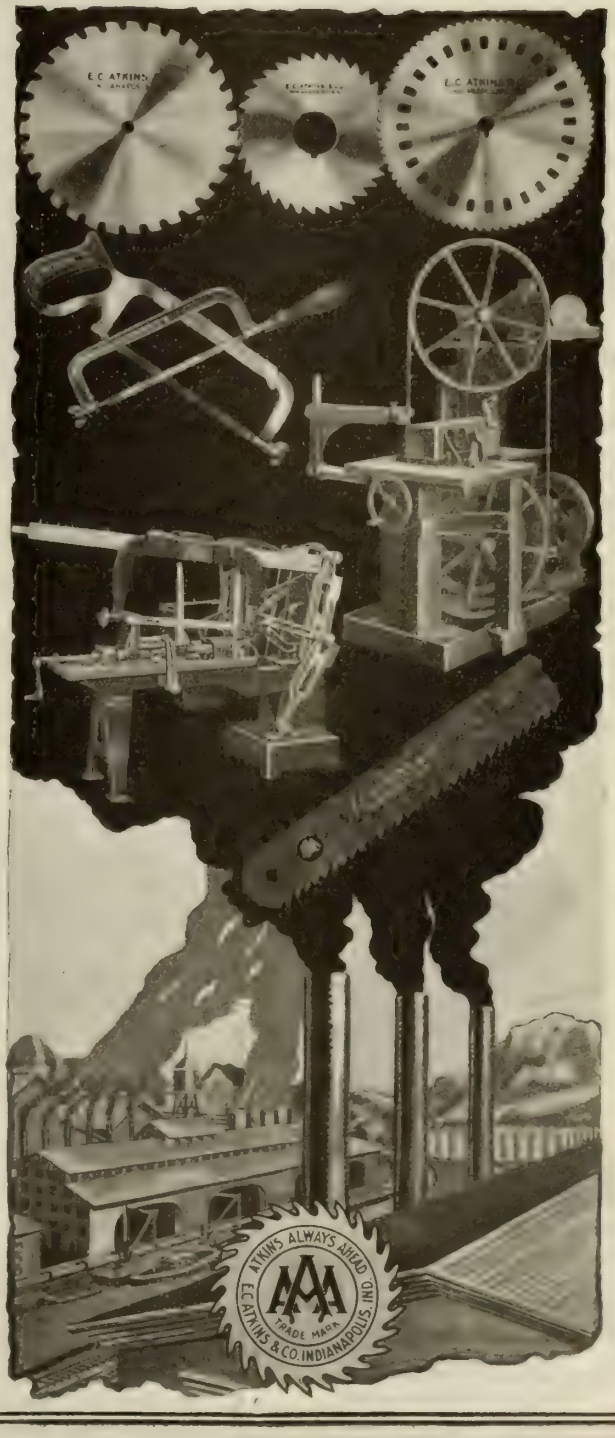
"As to the future,—it is bright. We are now working upon no fewer than eighty-two very promising industrial prospects, quite a number of which have already decided to come in when conditions revert to the more nearly normal.

THE TREND of iron and steel trade prices during the last nine years makes a very interesting study. The chart on this page, which is reproduced from Hardware and Metal, shows the comparative base prices on bar iron and steel year by year. The continued line represents the price fluctuations in Canada on bar steel, while the dotted lines indicates the rise and fall of primary base prices on bar iron, on the domestic markets. The index covers the actual prices, and thus the varying changes can be more clearly followed. The existing base price of $2.70, compares very favorably with the level of $2.25 in effect in January 1914. When freight rates, distributing and production costs, and various other elements are taken into consideration, it is readily recognized that the liquidation in steel prices is most thoroughly advanced.

Showing variation in iron and steel bars over a nine year period.

ATKINS METAL CUTTING SAWS

Business Looking Up?



Building contracts are increasing; metal stocks are being depleted; factories are resuming; metal saws and machines must be ordered.

ARE YOU READY?

SHOW CONFIDENCE IN THEIR REPRESENTATIVES

W. H. C. Mussen, of Mussens Ltd., has fulfilled an obligation he committed himself to in March 1915, viz., to pay off the liabilities which existed when the firm was placed in voluntary liquidation seven years ago. At that time, as at present, this firm was engaged in the sale of railway, mining and contractors, and municipal supplies, and in common with such enterprises, sharply experienced the business depression which affected Canadian contractors during that period of the war. Faced by the further difficulty of profitably disposing of the heavy stock on hand, Mr. Mussen, president of the firm, decided that it was then advisable to apply for the appointment of a liquidator. It was announced at the time that the liabilities of the firm totalled $300,000, while the assets comprising merchandise on hand, realty holdings, open accounts, and bills receivable, amounted to $550,000, or approximately $250,000 in excess of the liabilities. As the stock carried was not of a character to be readily placed on the market, particularly during a period of depression with no construction work in sight, the action taken was regarded as offering the greatest possible protection to the creditors.

At the time Mr. Mussen declared the liquidation proceedings were not being sought with a view of reorganizing the business, and he was not in favor of such a proposal unless it would be one under which the creditors would each receive a hundred cents on the dollar.

At the time of the liquidation, John J. Robson was appointed liquidator, which position he has maintained ever since. With the completion of his services as liquidator Mr. Robson will enter the services of the firm as auditor.

During the seven year period since 1915 they have received the support of the manufacturing firms represented by them at the time of liquidation, with one or two exceptions. With these exceptions, the firm continue to represent the firms who were their creditors. During the period several other firms requested the firm to represent them, showing the confidence in which they were regarded.

BRITAIN SECURES CONTRACTS IN RIVAL COMPETITION

"The present outlook in the engineering world still leaves much to be desired," said F. W. Field, H. M. trade commissioner at Toronto, to Canadian Machinery during an interview. "There are, however, certain features which give rise to hope for the future," he continued. It is known, for instance, that in certain recent important contracts in South America, a big Continental combine was obliged to surrender its deposit and cancel its obligations on terms, because it could not meet the tender price it quoted in the first place. There is a tendency for prices to rise in those countries where the exchange is depressed, and this is obviously making it very difficult for firm prices to be quoted.

Germany in particular is making commercial enemies by quoting low prices and then increasing them without stating reasons. As there is now less margin in many cases between Continental and British prices, customers in increasing numbers are coming to the United Kingdom for quotations.

Another feature which gives ground for hope is the way in which British firms are securing large contracts in competition with their rivals. A recent case was the order for grain-handling plant for South Africa, and just previously a big order for electric rolling stock in South America was secured. In each case the size of the order is stated to constitute a record for the country.

The locomotive builders are engaged on work for authorities, including the Crown Agents for the Colonies, the India Office, or the various Dominion High Commissioners. Wagon builders are in a favorable position and have a fair number of foreign orders. The contract secured by one firm for the supply of 1,000 tank wagons to Russia has eased the situation.

Considerable reductions in the price of metal have made it possible for manufacturers of rails, fishplates, fishbolts, nuts, dogspikes, steel sleepers, and signal equipment to complete overseas, and many of them report good orders recently secured. The increasing inability of Germany to secure raw materials from outside sources has obliged the manufacturers of that country to cancel many orders undertaken, and in the new invitation to tender the British supplier feels fairly confident, American, French, and Belgian prices having increased.

Most openings announced bring a ready response from the United Kingdom and an increasing readiness to face even the financial difficulties. The steady appointment of foreign agents, especially in South America, is an eloquent indication of the desire to do more foreign business.

Firms specializing in docks, harbors, bridges, and railway layout are in a good position. The home authorities have been steadily in the market for repair and extension work, and, as the number of contractors is not too great, the work, even when spread out, has assisted materially to keep them going.

The foreign market also has furnished work for them. The Yellow River Bridge in China, harbor construction and extensions at Candia (Crete), a sanitation contract in Salonica, canal making and bridge building in Belgium, etc., have all come the way of the British contractor, and for others they are confident of securing at least part of the work.

"This information is absolutely correct," concluded Mr. Field, "as it is based on news furnished me by the head office at London, in the department of overseas trade."

With a DUMORE High Speed GRINDER, jigs, dies, gages, bushings, etc., which have become warped during tempering, can be brought down to limits as close as .0001 in. This is but one of many ways in which DUMORE grinders serve thousands of mechanics daily.

Can 5,775 Be Wrong?

A SHORT time ago practically unknown—to-day, indispensable in the shops of 5,775 of the country's leading metal working industries! Such is the remarkable sales record of DUMORE High Speed GRINDERS.

What greater tribute to the efficiency of these grinders could possibly be given? Surely the judgment of over five thousand of America's foremost leaders of industry can be relied on!

You, too, can unhesitatingly choose a DUMORE as the *one* grinder for *all* your intricate grinding work. Their extensive use by many varied industries suggests their adaptability—their *continued* use in these various lines of work prove the efficient and satisfactory service they render.

DUMORE grinders are durably built in six useful styles and sizes. Combining perfect running balance with correct cutting speed, these compact, high-speed grinders work with a total lack of end play and absence of vibration. Speed and accuracy are assured on the most delicate jobs—increased output and decreased production costs are a certainty with one or more of these DUMORE grinders in the tool room.

Their many advantages and conveniences—the economy afforded by their superior performance—result in re-orders from eminent industrial experts everywhere.

Let DUMORE grinders eliminate the need of costly tearing down of original "set ups" in your shop. Let us show you, as we have thousands of others, how a DUMORE can convert wasted moments into productive hours. Ask your dealer or write us direct for information that will aid you solve your grinding problems.

PARKER VISES

They grip like a Grizzly.

A Real Swivel Base *Not* a Clamping Device

The patented swivel is adjustable to any point on the base and is held securely by an expansion ring. This provides a swivel base with all the strength of a solid back jaw.

Other Good Points

Semi-steel castings, removable jaws pinned from the top, solid steel strengthening bar in the slide, improved saddle and solid under portion, set screw and spring in handle, extra strong screw and nut.

Send for Folder No. 12.

KAELIN ELECTRIC STEAM GENERATORS

Their Field

Any mill or factory developing its own power which has surplus electric energy during the whole or any considerable part of the day.

Any mill or factory operating on bought power purchased on a "flat rate" basis, but which is not using all the power allotted to it.

Capacities

These Electric Steam Generators are built in sizes from 600 to 25,000 K.W., corresponding approximately to 60 to 2,500 Boiler horsepower.

They can be operated by alternating current only, and are built for voltages varying from 550 to 12,000.

Advantages

Their first cost including installation is low compared with any type of coal or oil-fired boiler plant.

They are safe, clean, easily regulated, require but little attendance and take up very small floor space.

They can be operated in parallel with existing boilers or can be installed close to their work.

Information and prices promptly submitted on receipt of particulars as to your conditions.

GOODELL-PRATT

1500 GOOD TOOLS

Don't think that Goodell-Pratt Tools are "Just as Good"

We don't want you to think that Goodell-Pratt Precision Tools are "just as good," as other kinds. If you are not thoroughly convinced that they are the best that you can buy, we don't want you to buy them.

Our Booklet "Tools for the Toolmaker" shows these micrometers. Get a copy.

We are sure that you can readily convince yourself that Goodell-Pratt Tools are better by making tests for accuracy, in comparison with tools of other makes. Take micrometers for instance: Before you buy a micrometer check it every .010 inch with a set of blocks and make sure that it is accurate throughout the entire length of the screw. Goodell-Pratt Micrometers are accurate because the lead screws are not stretched or "pulled."

Long years of accurate life are assured because every spindle and lead screw is made of one single piece of **tool steel** and runs in an extra long bushing.

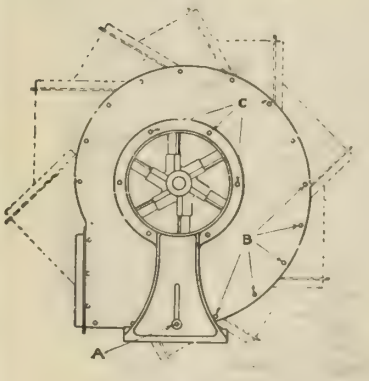
FIFTY YEARS OF QUALITY

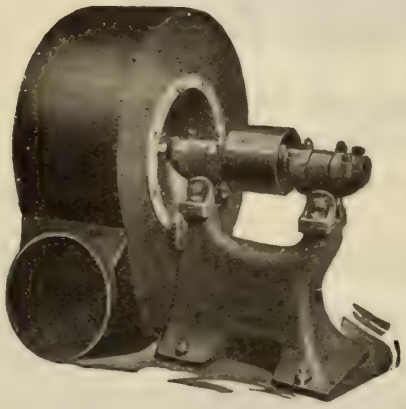
Canadian



The Canadian Standard Reversible Mill Exhauster will keep your shop clean, remove sawdust, shavings, fumes, gas or any loose materials and disagreeable odors.

Insurance rates can be reduced; floors and machines covered with sawdust, chips or shavings, increase the fire risk.

Insurance companies reduce the premiums where adequate precautions have been taken to prevent fires.



Blast Wheel — This wheel is so constructed that it will handle any kind of stringy material efficiently, such as sawdust, shavings, cotton lint. Will also handle gases, fumes, smoke, etc.

The Canadian Standard Planing Mill Exhausters have reversible housings so that the outlet can be adjusted instantly to any angle desired.

This eliminates necessity of crossed belts. Simplifies changes on alterations in piping or building.

The housing is of heavy rolled steel plate securely bolted together with angle irons, round cast iron outlet bolted to the housing. Blast wheel mounted on heavy cast iron spider.

Every fan carefully tested by running test at speeds in excess of that required.

Hand Protection
Means Better Work

Mitten Style No. 681

Steel-Grip WORK MITTENS

and work gloves give complete hand **protection** plus hand **comfort.** The same reinforcement (small steel ribbons over strips of tough leather) that protects the hand also gives so much extra wear that these mittens and gloves last almost indefinitely. Sewed closed with steel thread, they are absolutely rip-proof. The steel reinforcement does not interfere with flexibility. Your workmen equipped with Steel-Grips will dig in with a will.

Write us to-day for suggestions on your hand protection problems. We can save you money on your work glove purchases.

Hardware and Metal Circulation Dominates in Western Canada Because:—

Hardware and Metal is the *only* hardware paper giving a weekly market service from Winnipeg.

Hardware and Metal is the *only* hardware paper giving a weekly news section for Western Canada.

Hardware and Metal is the *only* hardware publication giving the trade in Western Canada a weekly market service from Montreal, Toronto, Hamilton, London and Pittsburgh —and Westerners are even more interested than any others in the activities in the primary markets of the East.

Hardware and Metal is the *only* publication in Canada giving the Western hardware trade a weekly service covering the activities of the hardware trade in a National way.

Hardware and Metal is the *only* hardware publication giving the Western Canada trade a weekly market service on paints, oils, varnishes, etc.

Hardware and Metal is the *only* hardware publication giving the trade any Western Canada weekly information regarding, "What Other Merchants Are Doing," Legislation, New Hardware Goods, Illustrated Articles on Display, Advertising, Etc.

Hardware and Metal during the twelve months of the year, supplies the Western Canada hardware trade with more market information, more new goods information, publishes more illustrations of window displays, store interiors, and retailers' advertisements than all the other Canadian hardware trade publications combined.

Incidentally, Hardware and Metal is the *only* hardware trade publication in Canada that will supply you with an Audit Bureau of Circulations statement, thus proving what it really has in the way of circulation in Western Canada.

MORAL—*If you are interested in Western Canada trade, advertise in the paper that is read by the Westerners and has gained its present dominating position in the West, as well as in other parts of Canada through 34 years of honest effort to give the trade each week the best in hardware trade newspaper service.*

There are many reasons why Hardware and Metal covers Western Canada as thoroughly

HARDWARE AND METAL

"Canada's National Hardware Weekly"

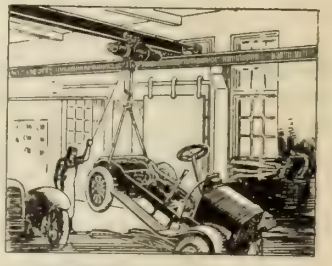
143 University Avenue, Toronto, Canada

Montreal Branch, Southam Building **Winnipeg Branch, Confederation Life Building**

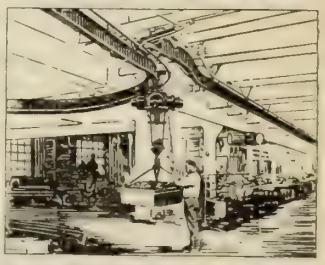
Published every Saturday since 1888. The only weekly hardware paper in Canada and the only hardware paper in Canada that gives you a circulation statement audited by the Audit Bureau of Circulations.

THE SHEPARD ELECTRIC LIFTABOUT

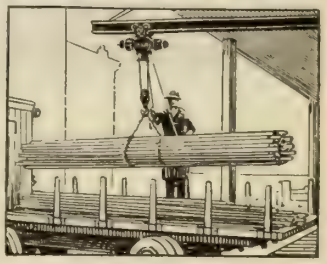
Big help at small cost



"THAT'S just what we've needed" has been said by hundreds in practically every business in all parts of the country when they learned of the Shepard Electric ***LiftAbout***. They sought a cheaper, faster way for moving loads and found it in this new small, but powerful, electric hoist. This "Big help at small cost" will pick up, carry, and put down the loads that must be moved in your business—save labor and take your load moving item from the debit to the credit column.



Whether the loads are heavy, fragile, or cumbersome, one man —any man—with a ***LiftAbout*** can handle them. No valuable floor space used, for a ***LiftAbout*** is easily and quickly installed to run on overhead I-Beam track—is always out of the way, but instantly available for service.



The Shepard Electric ***LiftAbout*** follows the same principles of design and construction that have made "Shepards" the most widely known and used electric hoists in America. It is surprisingly low in cost and economical to run, and makes power lifting available for every load moving job.

Investigate the time, labor, and money-saving advantages of the ***LiftAbout*** for your business. It will return handsome dividends on a surprisingly small investment.

Shepard also builds Electric Cranes and Hoists in capacities to 30 tons.

GALT, ONT.

Do Your Castings Cost Too Much?

A rearrangement of your patterns might cut their cost 25 per cent.; a different method of molding them might double your production at no increase in molding cost. We can advise you and we have expert metal and wood patternmakers who are able to make any changes that may commend themselves to you.

If you need some new Patterns

send us a sample, blueprint or sketch, and ask for our advice. It won't cost you anything. If our advice is good and commends itself to you, it is only fair to assume that our work will be equally satisfactory, and we need the work as badly as you need the patterns.

We are in a position to do turning, boring, drilling or other semi-finishing operations on castings supplied by us. Ask us.

We have for our and your requirements, a large stock of assorted White Iron Stars, suitable for light agricultural to medium weight machinery castings, while they last, at 8 cents per lb. F. O. B. Galt.

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

BUTTERFIELD

TAPS, DIES, DRILLS
MILLING CUTTERS AND REAMERS

Tools for Economical Production

Prosperity in Canada is inevitable. In due time all things will right themselves. Signs today in fact are encouraging. Now is the time to plan ahead for handling work of the future and competition will necessitate handling it economically, efficiently, and profitably. For your drilling, reaming, tapping and milling operations use only first quality tools—

ACME BOLT CUTTER

Cut Your Own Bolts on This Simple Inexpensive Machine

If you are a regular user of bolts you can effect a worth while economy by installing this 1½" Acme Double Bolt Cutting Machine. Like all **Acme** machines, it is built with distinctive features which result in easy operation and quantity and quality of production. It is equipped with an improved micrometer die adjustment within easy reach of the operator, which can be finely adjusted even while the machine is in motion. Die Heads are automatically opened and closed, and vise hand levers are adjustable on the vise screws for all diameter of bolts.

The Acme 1½-inch Double Bolt Cutter shown above threads and taps ⅜ to 1½-inch, either right or left hand. Machine cone, 8, 10, 12 and 14 inches in diameter for 3-inch belt. Speed of countershaft, with 16x4-inch pulley, 300 revolutions per minute. Geared 4½ to 1. C.S. cone, 8, 10 and 12 inches in diameter. **If this machine does not exactly suit your requirements, we have a machine that will.**

Where they tap nuts by the ton—

Records Are Kept of Tap Performance

These show that Pratt & Whitney Taps score highest on two counts. Time between resharpenings is longer than ordinary. They can be sharpened and resharpened and still retain their original size long after other taps have gone to the scrap pile.

The "Con-eccentric land," an exclusive Pratt & Whitney feature — coupled with superior workmanship and rigid inspection both of the steel and the taps—are the secret of their long life.

The Hammer With The Human Stroke

HEADS RIVETS COLD

Heads 'em tight or loose, flush, countersunk, or finishes heads any shape desired, and at the rate of:
A rivet a second, sizes up to 3/16".
A rivet in two seconds, size ¼" to ⅜".
A rivet in three seconds, size 7/16" to ⅝".
And on special order we build machines to handle rivets up to 1½" with proportionate rapidity.
Built in eight sizes.
Besides riveting, the High Speed Riveting Hammer does all kinds of peining, swaging, upsetting, etc.
Send us sample assembly parts with rivets or sketch of your work,
and
Let us shoulder your riveting problems.
Send for the High Speed Hammer Book.

Mechanical Goods of Proved Value

The right machine or supplies for your particular requirements; experienced men who can give you definite information regarding your special problems—both may be found at the nearest branch of Canadian Fairbanks-Morse.

Fairbanks-Morse products, designed by our own engineers and made in our own factories, have built up a world-wide reputation for reliability.

Canadian Fairbanks-Morse agencies comprise the world's leading manufacturers of mechanical goods—of machines and supplies that have the fullest endorsement of the largest number of users.

Here Are Some of the well-known Lines we Handle:

- Fairbanks Valves
- Brown & Sharpe Machine Tools
- McDougall Lathes
- Gisholt Turret Lathes
- South Bend Engine Lathes
- Landis Threaders
- Graton & Knight Leather Belting
- Yale Chain Hoists
- Esterbrook-Allcard High-Speed Drills
- Norton Grinding Wheels
- Dick's Balata Belting
- Fairbanks-Morse Motors
- Durabla Packing

Each department is ready to extend the fullest co-operation in the solution of your problems because it is in charge of experienced men who know how best to meet your particular requirements.

DO YOU Manufacture Industrial Equipment?

Are you a manufacturer of twist drills, hack saws, mechanics' tools, wire guards, bolts, rivets, paints—do you manufacture lines of any description that can be used in machine shops, metal-working plants, power plants or foundries? If you do the publications you see illustrated here (Canadian Machinery, Canadian Foundryman, and Power House) can build a bigger demand for your products.

This group of technical newspapers is read by the men who are prospective buyers of your lines. You can bring to the attention of these men the reason why they should demand your goods when purchasing from their dealers. You can effectively do this by placing a message in the paper which serves the field in which your products are sold.

CANADIAN MACHINERY AND MANUFACTURING NEWS is published weekly and covers the machinery, iron and steel and general metal-working industries of Canada.

POWER HOUSE is published semi-monthly; it serves steam, electrical, water and gas power plants, and the power houses of all general manufacturing plants.

CANADIAN FOUNDRYMAN AND METAL INDUSTRY NEWS is published monthly; it serves the grey iron, steel and non-ferrous foundries.

Each one of these publications reach proprietors, managers, purchasing agents, foremen—the men who direct the purchasing of goods. A message to these men in any of the MacLean Technical Newspapers is certain to have a strong influence.

Write for complete Data.

"Belting trouble ends where D.K. McLaren's Belting begins"

Changing Belts is Like Changing Men---*Costly*

BELTS are very much like human workmen. Every time they are changed production is impaired and costs mount to enormous proportions. The very act of changing and splicing a belt means a costly hold up of men and machines. Hundreds of dollars a year are wasted in this way.

The point then is to choose a belt which will have long-time usefulness with minimum attention. Such a belt may be obtained in the same manner you choose a shop superintendent.

You pick a shop superintendent because of his greater ability over his fellow workmen. He is worth more to you and you pay him more. Likewise a good belt that saves labor and saves power can not be purchased at a low price. "Good and Cheap" are never found together. Service is the factor to consider. That is why men who appreciate real belting economy are regular users of D. K. McLaren's Genuine British Oak Tanned Leather Belting.

D. K. McLaren's Belting Saves Repair Time

It stands to reason that a belt can not give long, labor-saving service unless it is built of the highest quality leather. Every D. K. McLaren leather belt is made from the world's choicest steers—and only the back portions are used. The British Oak tanning process imparts great strength, flexibility and freedom from stretch.

These are the reasons why D. K. McLaren's leather belts give such ideal service—why they are not cheap but economical. May we send full details?

Better Illumination Means Greater Production

Output Increased and Accidents Reduced by Using Improved Lighting Systems—Measuring Instrument Determines Accurate Requirements for All Conditions—Proper Type of Reflector Eliminates Glare

INTO THE period of only two score years has been crowded the evolution of electric lighting. In this short space of time, we have seen electricity almost entirely supplant oil and gas wherever electric service has become available. The electric lamp has definitely established itself as the one most desirable illuminant. The advantages which have brought electric lighting to the fore have been largely those of safety, convenience and reliability.

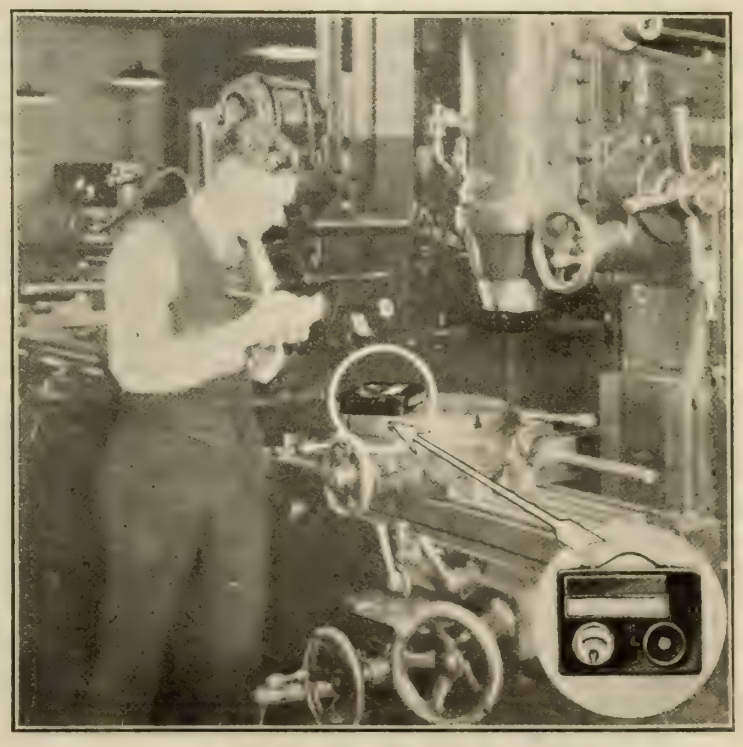
Applying this knowledge to industry one has only to compare the good lighting installations with the many bad installations, to realize that eliminating delays—and so increasing production and doing better work—through improved lighting is something more than a theory.

Imagine yourself the workman in a well illuminated plant. The clearness with which details are revealed, the softness of the light, the absence of serious direct and reflected glare, and the cheerful, stimulating appearance of the room will then take on a new and more emphatic meaning. Not only are the attributes of improved lighting mentioned, responsible for substantial increases in production, but for marked decreases in spoilage, and for greatly reduced accident hazard as well.

Light Measurement

At the time new interest in lighting was beginning to be felt, came the development of an instrument called the "Foot Candle Meter," which makes the measurement of illumination a quick and easy matter. A glance at the scale of the instrument shows the intensity directly in foot-candles, the accepted unit of illumination measurement. The foot candle meter is a simple, inexpensive instrument, measuring 8 by 6 by 1½ inches, and weighs approximately three pounds in its leather case. The meter has a stationary comparison lamp and scale. The brightness of this comparison or standard lamp is regulated by a small rheostat and volemeter. When the standard lamp is held at the proper brightness by the volemeter reading, the spot on the scale that appears to fade out is receiving an equal amount of illumination from the comparison lamp and from the outside source of illumination. Thus indicating directly the value of the illumination. This instrument is the "yard stick" of illumination and is as necessary in any large plant as are scales for checking up the weight of merchandise purchased. Lighting is not a matter of wattage consumed but of how much light you get from that wattage.

By actually measuring the light right down on the job, as indicated by the illustration, guess work is eliminated, and the plant manager can make sure that his men are getting sufficient light to enable them to see quickly and clearly and comfortably for long periods.



By the occasional use of the foot-candle meter, when on a trip through the plant, the executive can check up and make sure that the lighting is performing its function in the production program.

Definition of Terms

Briefly, one lumen on one square foot gives one foot-candle.

The lumen is the unit of quantity of light, and is used to measure the output of a lighting unit or the illumination falling upon a surface. It is the quantity of light which will fall on a surface one square foot in area, one foot distant from a light having a value of one candle. All Mazda lamps are rated in lumens according to total light output.

The foot-candle is the unit of illumination. It is the illumination produced by one lumen per square foot falling upon a surface, and is usually measured by

Determining the quality of illumination, by means of measuring instrument.

the foot-candle meter. It is one candle power at a distance of one foot.

At two feet the illumination would be one-fourth foot-candle (not one-half foot candle); at three feet, one-ninth foot-candle, etc., in accordance with the law of increase squares. It should be noted that candle power refers to strength or intensity of light emitted from the light source, whereas the foot-candle refers to the strength or density of illumination falling upon the object or area illuminated.

Foot-Candle Illumination

The desirable illumination varies rather widely, depending upon the conditions in any particular installation, such as accuracy of the operation and fineness of detail to be observed. One need have no hesitancy, however, in stating that more light than is generally used today may be used economically and profitably.

Daylight, on a bright day will easily measure up around 200 foot-candles; the usual run of factory interiors will measure under artificial light in the neighborhood of three foot-candles. Obviously, in a well designed artificial lighting system, there is little likelihood of there being such a thing as too much light.

Don't mistake glare for light. Glare is light out of place. Correct this by the use of the proper type of reflector and use bowl-frosted lamps. Shade the lamp and direct the light.

Three general levels of illumination may be considered:

5 Foot-Candles:—Satisfactory for work of a coarse nature, such as rough assembling, rough packing, coal and ash handling, and similar duties, where the eyes are not called upon to see small details quickly and accurately. This intensity of illumination would also prove ample for lighting warehouses, storerooms and aisles and passageways, which are to be kept free from obstructions. The light would be enough to dispel any sense of gloom.

10 Foot-Candles:—Considered good lighting for most kinds of work, including jobs like fine forging and welding, moulding and core-making, medium bench and machine work, grinding, buffing and polishing. The light value however is not sufficient for examination of fine details.

15 Foot-Candles:—Is excellent lighting, and will be illumination enough for most classes of work. In addition to permitting quick and accurate execution of all work except the most exacting, lighting of this kind stimulates the workman and makes for fast and accurate production.

Practically every shop or mill requires artificial light, at least a part of the time, and no factory executive can afford to overlook the opportunities afforded by good illumination and lighting improvement.

In the next issue information will be given and suggestions made as to the methods that may be employed to calculate and improve general illumination design where inadequate lighting now exists.

John T. Scott.

JOHN T. Scott, the author of this article, was born in Essex County, England, in 1885. At Birkbeck College he received a general education going from there to London University for his technical education in electrical engineering.

After graduation, he joined the staff of Marconi Wireless Telegraph Co., where for three years he was engaged both in the test rooms and manufacturing plant.

He has also had several years of commercial engineering experience in Europe, including Scandinavia, France and Germany. During the war he had charge of munition production at the plant of the J. G. White Engineering Corporation.

For the last two years he has made a special study of lighting and illumination problems. He is at present engineer in charge of standardization work at the Sunbeam Lamp Work's Division of the Canadian Electric Co., Toronto.

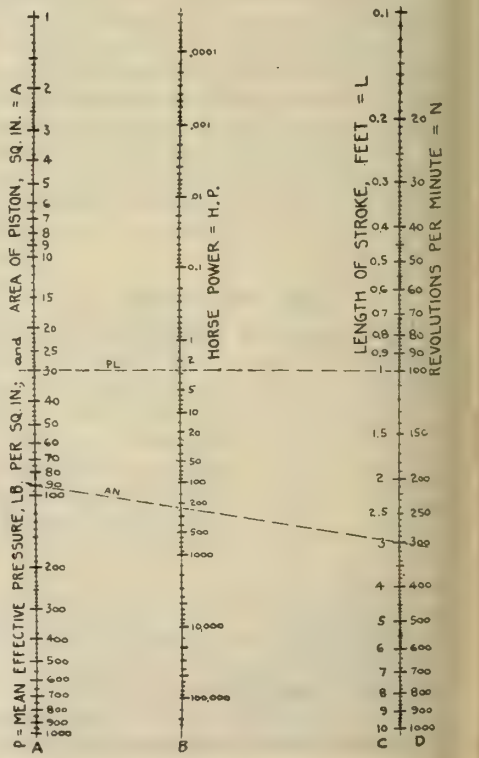
Mr. Scott is a member of the Illuminating Engineering Society in Toronto and New York, also a member of the lamp committee of the Canadian Electrical Association at Montreal, and knows his subject thoroughly.

HORSE POWER CHART

By W. F. Schaphorst

This solves the much-used formula

$$\text{Horse Power} = \frac{\text{PLAN}}{33{,}000}$$



For example, what is the horse power of the crank end of a steam engine, the mean effective pressure being 30 pounds per sq. in.; the piston area being 90 square inches; the length of strokes one foot; and the number of revolutions being 300 per minute?

Connect the 30 (Column A) with the 1 (Column C) and locate the intersection with Column B. Then connect the 90 (Column A) with the 300 (Column D) and locate the second intersection with Column B. Now locate the mid-point between the intersections in Column B. It is a simple matter to find the mid-point by folding a piece of marked paper, by means of a pair of dividers, by measuring with a rule, or any other easy way of bisecting a line.

The mid-point, Column B, gives the horse power of the crank end as being very close to 25 h.p. Multiply it out "longhand" and you will find the exact power as given by the formula to be 24.5 h. p.

The chart will therefore prove itself to be highly useful in checking over your figures, in case you are desirous of being absolutely sure of your computations. Generally, it will be found close enough for most practical purposes.

It will be noted that the range of the chart is very great indeed—running up to over 100,000 h. p.—thus including every steam engine ever built. The lowest range is 1/10,000 of a h.p., which would be a most delicate toy engine.

Simple Cost System Proves Efficient

Checking Progress of Work—Following the Job Through the Factory—Keeping Record of Rejected Parts—Using Both Sides of Card Gives Complete Story of Piece

By J. H. MOORE

THE IMPORTANCE of a careful check on parts passing through the factory is unquestioned. Unfortunately, there exists a laxity in this respect, with the result that in many cases the finished piece costs more than it should. A time and operation checking system should be as simple in character as possible, otherwise confusion and dissatisfaction will result. For example, the W. H. Banfield Co., Toronto., have adopted a checking and routing system which is very complete yet easily handled, and believing manufacturers will be interested in this method, we have selected some sample cards used in the system which will be of special interest.

When Order Comes In

Upon an order being received, the clerk fills out an order form as shown at Fig. 1. This is made in triplicate, white, yellow and blue, one staying in the office, one going into the production department, and the other to the shipping room. When shipment is completed the head shipper returns his copy to the main office, when the order is marked closed.

Suppose we follow the order form which went to the production department. From standard operation sheets this department makes out three cards as shown at Fig. 2. These are all marked the same with the exception of the department number, one going to the inspection department., one to the control board room, and one following the job as it proceeds through the factory. A sheet on lighter stock, but made out exactly similar, stays in the production department as a record.

Studying Fig. 2 we find that the number of each operation is given, the nature of the work, and the department in which the work is finished. Thus, operations No's 1 to 4 are completed in department 2, operation No. 12 in department 32 and so on. The order number is given in upper left hand corner, also the quantity required, and spaces are provided to mark in the finished pieces O K, or rejected, also the date completed. The part number, and name

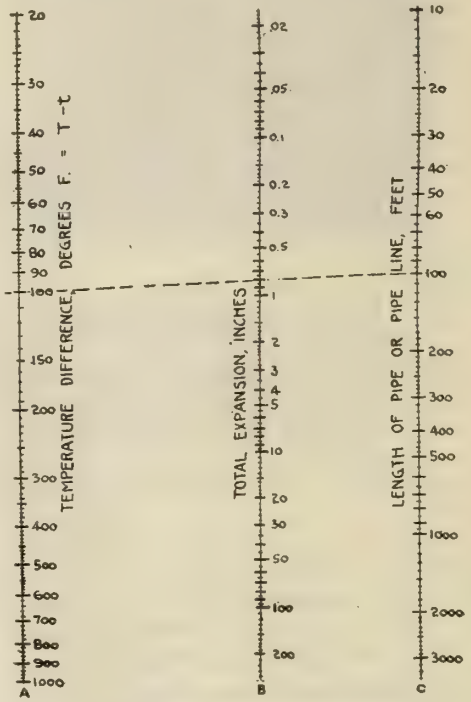
Fig. 1.—(Left) Receiving clerk's order form made out in triplicate, 3 colors. Fig. 2—(Right) Route card showing details operations and complete record on each job.

are provided for, and at the bottom of card, the date issued can be noted, the time scheduled to start, finish, etc. Thus, on one card we have the complete story of the piece. The reverse side of the same card looks like Fig. 3, this registering the quantities made in each operation and passing forward to the next department, or stores as the case may be. This of course acts as a further check on the pieces.

Fig. 4 shows the style of standard operation card kept in the production department files, and it is from this card that all the necessary information for starting an order is obtained, including nature of material required, weight, etc.

After the work has been completed, the control board operator collects the follow-the-job and inspection cards, checks off the quantity claimed to have been completed, with the quantity delivered to stores, and then after filling in his own control board copy, marking all particulars regarding scrap, rejections, etc., he turns in all the cards to the production department who close out the order started, as registered on the back of the card shown at Fig. 4. The illustration Fig. 5 depicts a portion of these entries and shows the style of the card. This completes the record on the job from start to finish, so far as the production department is concerned. The control board copy bearing finished details is marked order closed, and forwarded to cost department, who in their turn close out their records and arrive at the finished cost.

In order that readers will understand how rejections are taken care of, we show at Fig. 6 a sample rejection slip. The parts are accounted for on this form, whether the pieces are scrap or suitable for rectification. If the latter, they are sent to the detention stores until they accumulate sufficient quantity to warrant setting up machine for rectifying. Credit is given for this quantity at a value leaving sufficient margin for the necessary expense of rectifying. One copy of this form is sent to cost department, one stays in the production room, and another remains with the rejects.



From the foregoing brief description it will be seen that at any time the pieces are under control. The follow-the-job card cannot leave a department before all the pieces are out of that department, and all particulars relating to the part are always noted on the back of the card. From start to finish this follow up system is simple and effective.

A Useful Expansion Chart

By N. G. NEAR

MACHINISTS will find this chart useful for determining the expansion to be allowed in piping rods, tubes, etc., for various temperature differences without doing any "long-hand figuring" whatsoever.

To use the chart simply lay a straight-edge across it once, or stretch a fine black thread across it, as indicated by

the dotted line, and the problem is solved without further ado.

For example, a certain pipe line is installed which is 100 ft. long. It will be subjected to a temperature variation of 100 degrees F. What will be the total expansion in inches?

Connect the 100 degrees temperature difference, Column A, with the 100 ft. length, Column C. The intersection with Column B gives the answer as 0.8 inch. That's all there is to it. Very simple indeed.

Inversely the chart can be used for determining the allowable temperature difference where a definite amount of space is available for expansion and contraction. Thus if the length of the pipe line is 100 ft. and the allowable expansion is 0.8 inch the same line would show that a temperature difference of 100 degrees F. would be the limiting amount.

Also, if the factors in Columns A and B are known, the unknown in Column C is immediately found. In other words, if any two of the factors are known the third factor is very quickly found, and without any computing whatever.

It will be noted that the range of the chart is wide enough to take care of almost any expansion or contraction problem that the machinist may have to contend with. The temperature difference, Column A, varies all the way from 20 degrees to 1000 degrees. It is very seldom, if ever, that we have as high an amount as 1000 degrees. The length of pipe line, also, is great, varying all the way from 10 ft. to 3000 ft., or more than a half of a mile. And the total expansion between these limits varies all the way from 0.02 inch to 200 inches. It is interesting to note that if we had a pipe line 3000 ft. long, with a temperature difference of 1000 degrees, the expansion would be over 200 inches.

About 88 per cent. of the world's supply of asbestos is furnished by the Province of Quebec, and about 85 per cent. of the world's demand for nickel is mined in the Sudbury and Cobalt districts of the Province of Ontario.

How Industrial Accidents Can Be Prevented

Compensation Last Year Amounted to Over Six Million Dollars —Who is Responsible?—How Hazard Can be Minimized— Worker's Attitude of Mind Often the Cause of Accident

By SAMUEL PRICE

YOU may mitigate the results of accidents, but this does not make up for the pain and suffering. Compensation does not restore the life destroyed, or the limb lost or crippled. These pertinent truths were forced home by the author during the recent joint safety convention held in Toronto, where he spoke on "Ontario's Accident Prevention Policy." In telling about the accidents that have been happening in Ontario industries he said:—

The casualty list is a heavy one. The sufferers very numerous. The only redeeming feature is that some relief is now provided for all accidents happening in industries covered by The Workmen's Compensation Act. When a workman is killed or injured in his employment, justice as well as humanity requires that some recompense shall be made, and the Ontario Act, I am glad to say, is the most liberal among those of the provinces in the benefits that are provided. That help is being given to those who suffer as the result of accidents is a great satisfaction, and the appreciation that is shown by many who would otherwise be in need is very gratifying.

Nearly 500 cheques are being despatched daily to various parts of the province, bringing support and relief to workmen who have been crippled or injured in their employment, and widows, children and parents of workmen who have been killed. More than 100,000 people(including workmen's families) are every year more or less dependent upon these payments for their maintenance. About $21,000 per day is being awarded in benefits. The total for the past year was $6,189,000. For the seven years the present act has been in operation the total benefits have amounted to nearly $28,000,000.

Compensation Does not Restore

But though we thus relieve and mitigate the results of the accidents, and employers are called upon to furnish the money, we do not wholly make good even to the workmen and their dependants the monetary loss, to say nothing of the pain and suffering, which they sustain. Compensation does not restore the life that is destroyed or the limb that is lost or crippled; and no matter in what proportions he direct loss m be borne by workmen and employers the result is economic waste, with usually everyone very much the loser. The producing power of the country is also diminished.

In an industrial army of about 450,000 workmen, 45,191 accidents were reported in 1921, 386 of them fatal. There were 272,000 accidents, 2,784 of them fatal, during the seven years' operation of the act. This is a total equal to the combined population of Hamilton, Ottawa, and Windsor.

This is the accident record in Ontario for industries covered by the The Workmen's Compensation Act. There was an average of 151 accidents a day last year—one about every three minutes of the working day. This is one accident for every 10 workmen. It would take only 10 years at this rate to have an accident for every workman in employment. The accident frequency or rate per hundred of full year workers has not changed greatly during recent years. The comparison for compensation cases is: 1917, 6.57; 1918, 6.54; 1919, 6.56; 1920, 6.97. There has been a decrease in the frequency of death cases; permanent disability cases have remained about the same; temporary disability compensation cases have slightly increased; and medical aid only cases have very considerably increased.

Less than one per cent. of all the accidents reported result in death; about 6 per cent. in some degree of permanent disability; about 56 per cent. are temporary disability cases involving compensation; and about 37 per cent. involve medical aid only and no compensation, the injury not disabling the workman for as much as seven days but requiring the services of a doctor.

Cost of Accidents

The most costly class of case are the permanent disabilities, involving nearly half the total accident cost. For 1920 the permanent disability cases in schedule 1 industries (omitting the odd figures) cost a total of $2,143,000, or an average of $990; the death cases cost $933,000, or an average of $3,779; the temporary disability compensation cases cost $1,617,000, or an average of $71; the cases involving medical aid only cost $78,000 or an average of $5.00. The average cost of all compensation cases was $195, of which $26 was for medical aid. The average cost of all accidents was $123, of which $18 was for medical aid. About 15 per cent. of the total accident cost is for medical aid.

In figuring the accident cost, the amount necessary to take care of pension cases as long as the pensions will last is included, the amount of assessments collected being what will be necessary to make payment in full for the accidents that have happened. The fund set aside for the payment of pensions that have been awarded is sometimes erroneously referred to as a reserve. The only real reserve that is set aside is a small fund, known as Disaster Reserve (one per cent. of assessments), now amounting to $218,000, intended to assist in meeting any catastrophe or extraordinary call that might be too heavy a burden on any class of industry. In nearly half the temporary disability cases the workmen get back to work within two weeks after the accident, and in over two-thirds of them within three weeks. The average time loss in the temporary disability compensation cases for 1920 was 19.62 days. This average time loss has slightly decreased since the early years of the act, the figures for each year from the commencement being 20.83, 22.95, 21.33, 19.75, 19.66 and 19.62.

The kinds of injuries are very numerous and variable. It may be of interest to mention some of those that most frequently occur. There were 151 permanent and nearly 800 temporary eye injuries; 272 permanent leg and foot injuries; 156 permanent arm injuries; and 1669 permanent hand or finger injuries; among temporary disability cases there were over 8,000 cuts, lacerations, and punctures; over 5,000 bruises, contusions, and abrasions; 1,800 fractures; 2,500 crushes; 1 500 sprains, strains, twistings, and wrenchings; 1,700 burns and scalds; and nearly 200 dislocations.

It is a significant fact that less than one-third of all accidents reported are on machinery. The guarding of dangerous parts of machinery, while highly advisable in its way, is not the only way in which industrial hazard will be materially reduced. Workmen must educate themselves to the imperative need of exercising the habits of greater carefulness and thoughtfulness in the performance of their respective duties.

Causes of Accidents

Stepping on and knocking against objects caused 2,455 accidents during the year; letting objects or material fall caused 1,341; the falling of workmen caused 3,952; 10,609 accidents resulted from the handling of objects or material, in loading carrying, piling, etc. How are these accidents, which may be referred to as arising from the general hazard rather than as arising from machinery or the particular nature of the industry, to be eliminated or reduced? First, I think it is important that there should be proper surrounding physical conditions, suitable space, efficient or-

---

Author is chairman of the Workmen's Compensation Board and delivered this address before the recent Joint Safety Convention at Toronto.

ganization, and orderly arrangement of the factory or plant. I think a still more important thing is the state of mind and attitude of the workers, foremen, superintendents, and managers. Is there sympathetic co-operation in the work and in the desire to avoid mishaps? Is it looked upon not only as a misfortune but also as a reflection upon workmen, foremen, and management to have preventable accidents? Is the employer actively in earnest about preventing them? Does he hold his superintendents and his foremen personally responsible when they happen? Will he deal with them as sternly for having workmen under them carelessly and needlessly injured and maimed as he would for having his machinery or material carelessly and needlessly broken or destroyed? I believe this is the most important factor in accident prevention.

The prevention of industrial accidents can only be successfully achieved through the mutual understanding and co-operation of the executive heads and the workmen. It is not sufficient to issue printed instructions regarding certain hazards. The workers should realize that those higher up are personally interested in their welfare and should therefore endeavor to see that every possible precaution is taken at all times.

For illustration, it is a very striking fact that many accidents—a very undue proportion—happen to new men just commencing to work in an establishment, often within a few hours, frequently within a few days, after starting. Here is a hint to employers and foremen. Take a little pains, show consideration and sympathy with new hands till they become accustomed to their surroundings. So far as machinery goes, the old offenders, abrasive wheels, saws and presses and stamping machines, continue to take their heavy annual toll of eyes, hands, and fingers, and sometimes the lives of workmen. Goggles, guards, and carefulness would rob these three offenders of much of their destructiveness.

Another very frequent cause of accident is molten metal getting into workmen's shoes, which could be prevented by proper footwear. All these are things that have been frequently discussed before, but until there is greater diminution in such accidents they cannot be too often mentioned. One other particular kind of accident I will refer to, namely, the injury of comparatively young boys employed upon machinery—fingers, hands, or arms lost upon presses, saws, planers, etc. These are far too frequent. This should have the earnest attention of every employer.

Make Use of Information

The Board supplies to your accident prevention associations particulars of all compensational accidents as soon as reports are received, giving name, address, age, occupation, nationality, marital condition, and language of the injured workman; name, industry, and location of plant of the employer; date, hour, and cause of the accident; and the nature of the injury. This information can be used to great advantage by these associations and their inspectors, and I am sure, with the energy and earnestness now being displayed by the management of these organizations, it will be made good use of in observing and studying the causes of accidents and suggesting and applying means of prevention.

Next thing in importance to prevention of accidents is to prevent or mitigate their evil consequences. Whether a cut, scratch, or other wound is to become infected will largely depend upon the prompt and efficient application of first aid treatment to sterilize the wound and keep out infection. Employers should provide first aid equipment in their factory or plant and have it in charge of someone competent to use it, and should insist upon workmen immediately reporting wounds, even though slight, and having them attended to. The importance of this is not sufficiently realized.

The figures respecting blood poisoning cases are startling. From six to nine per cent. of all compensation cases have infection at some stage, and the cost of such cases is at least ⅛ of the total accident cost, amounting probably to ¾ of a million dollars a year. In 1920, the nine per cent. of the blood poisoning cases included 56 cases of joints immobilized by infection, 28 amputations due to infection, and no less than 24 deaths due to infection. This is a terrible toll, and without doubt much of it could be prevented. The last complete figures are very disappointing. They show a very serious relapse. There had previously been a distinct improvement over earlier years. The percentages from 1915 are, respectively, 8.8., 8.3, 6.2, 6.7, 6.7, and 9 per cent. By far the worst record was that of the packing house class, in which the percentage for 1920 was 24.86. It showed an improvement and then a relapse similar to the other industries generally.

This surely calls for energetic and drastic measures. The Board's regulation (88) requires employers to provide a proper first aid service and to post up notices warning workmen of the danger of blood poisoning and requiring them to immediately report cuts, punctures, scratches, and burns, to the office or first aid officer for attention. These notices (in different languages) are furnished by the board upon request. Another very important branch of first aid is resuscitation in case of drowning or electric shock, especially the latter. Many a life can be saved by the prompt use of proper and persistent measures of resuscitation.

Skilled Doctors

Then there is the question of skilled medical or surgical service where there is any serious injury. Whether a broken bone, a severed tendon, or a mangled member is to result in loss or impairment of function, depends in many cases upon the skill and care of the surgeon who is looking after the case. This, as we all know, varies very greatly, and it is good business and a great benefit to the workman to make sure that none but the most capable and painstaking surgeons are called to deal with accident cases.

Malingering

I have mentioned as means of mitigation of the effect of accidents, efficient first aid measures and skilful surgical attention. There is one other thing I would like to say a word about—getting the injured workman back to work. This will no doubt at once suggest the disagreeable word "malingering." But it is not wise to run away from disagreeable questions. Every care should be taken to see that workmen get back to work when they are able. Employer, doctor, workman, and Board, should all co-operate to this end, and here again is to be emphasized the importance of having doctors of the highest integrity and character. Malingering should not be tolerated. In the end it would be workmen generally who would suffer most by anything that would bring discredit upon the act. No doubt at the present time there is more than ordinary danger of malingering, but, frankly, I do not believe it prevails, or ever has prevailed, to any serious extent under our Ontario Act. The fact that the average time loss has not increased and that medical aid cases have increased more in proportion than compensation cases confirms this view. There is often too much loose and unwarrranted talk about malingering. When I hear it mentioned I always ask for instances or particulars, and we never fail to investigate any specific case that is brought to our attention. Generally, the complaints turn out to be unfounded or to have arisen from a misunderstanding, but where imposition or fraud is discovered it is sternly dealt with. Prosecutions have been entered and convictions obtained against both workmen and doctors for obtaining or attempting to obtain money under false pretences.

Rehabilitation

Of far greater importance is the problem of finding something for a willing but crippled workman to do, and often a crippled workman is in need of a little encouragement. Nothing I think raises an employer more in the good opinion of his own workmen and of the community generally, or conduces more to good feeling and relations than sympathetic interest and consideration for the workman who has been crippled in his employment. We have been hearing much in recent years about rehabilitation. I think one of the most useful improvements that could be made in our Act at the present time would be a provision enabling the Board to do a little more than it is now able to do in the matter of rehabilitation. The expense

(Continued on Page 32)

Turning Long Piston Rod in Turret Lathe

Unusual Job for This Type of Machine—Special Form Tools for Turning Tapers—Complete Rod Rough Turned Ready for Grinding in Thirty Minutes

AN UNUSUAL and interesting job of turning in a turret lathe is shown in the accompanying illustrations. The work is a large locomotive piston rod made from 3⅞ in. black steel bar with a tensile strength of 80,000 lbs. The finished rod is 50 in. long, and is turned all over ready for grinding in one-half hour.

In most engineering works, a piece of the dimensions shown would be machined on a centre lathe, but the above time indicates that the turret lathe method can be adopted with satisfactory results. The saving effected is not offset in any way by a costly equipment, as the only special tools used are two form tools for turning the short taper.

The rods are delivered to the turret lathe cut to length and centered at one end. At the first operation, shown in Fig. 1 the rough bar is gripped in a 25 in. Coventry chuck with the centred end outwards. The jaws hold on about ½ in. of the bar, and while being tightened up, the outer end is centralized and supported by a dead centre in the turret. With the centre still in position, a knife tool in the square turret prepares the end of the bar to allow the roller steady turner to be used. The whole of the bar up to the shoulder is then turned down to grinding size in one cut, using the roller steady turner. During this operation a form tool is fed in from the square turret to rough out the short taper.

The dead centre is then reapplied and the long taper at the other end is turned from the square turret, using the standard taper turning attachment mounted at the back of the saddle. The square turret is again used to face up the end form radius under the shoulder, this completing the first operation in 21 minutes. At the second operation shown in Fig. 2. the partly finished rod is gripped in soft jaws at the back of the short taper, while the other end of the rod is supported in a bush inside the spindle. This ensures the two ends being true with each other. The end is first centred, then the thread diameter is turned using the roller steady turner. A roller steady ending tool faces the end to length after which the thread is cut with a 3 in. Coventry diehead. With the dead centre in position the short taper and the extreme end are finish formed, with a tool held in a massive holder on the rear of the cross slide.

This completes the second operation which occupies 9 minutes. Thus this large piston rod is machined ready for grinding in 30 minutes.

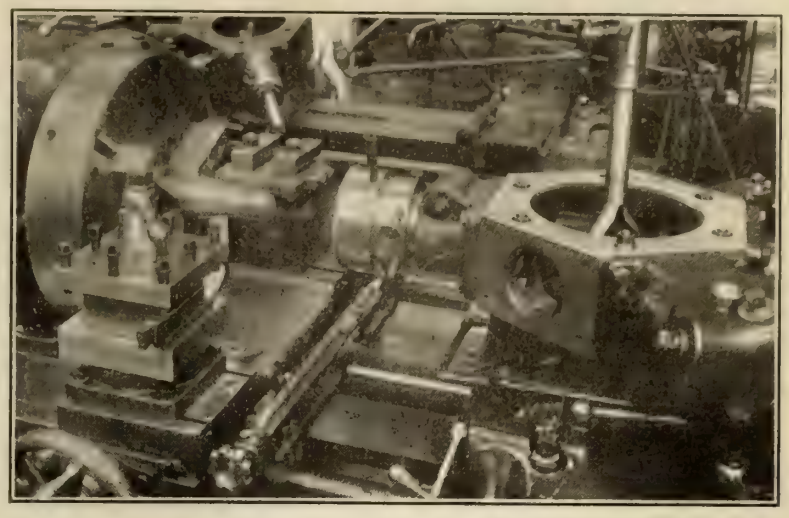

Fig. 2.—Tapering and threading piston end.

NEW BRITISH STEEL

One of the most fascinating phases of the steel industry is the development of special alloys in which chromium and nickel are employed. Alloys of this kind have come into fairly general use for motor car and aircraft work on account of their great strength and toughness, but they are liable to become brittle after tempering. This tendency can be corrected by quenching—that is to say, rapidly cooling—the metal in either oil or water. Unfortunately such quenching may cause distortion of the material, which can be straightened out only by mechanical means which strain the metal. In order to remedy this condition of affairs a British firm instituted a special research which has led to the production of a new alloy which has even better mechanical properties than the ordinary alloys and is not liable to brittleness.

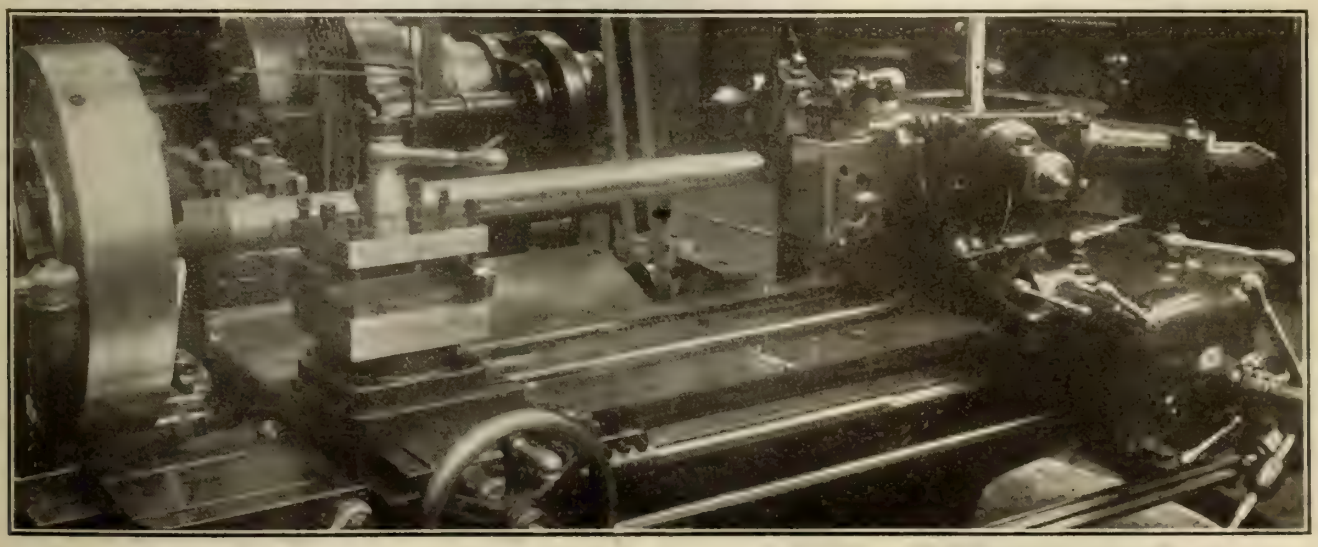

Fig. 1.—Machining 50 in. piston rod on turret lathe.

Practical Mining Methods Basis of Instruction

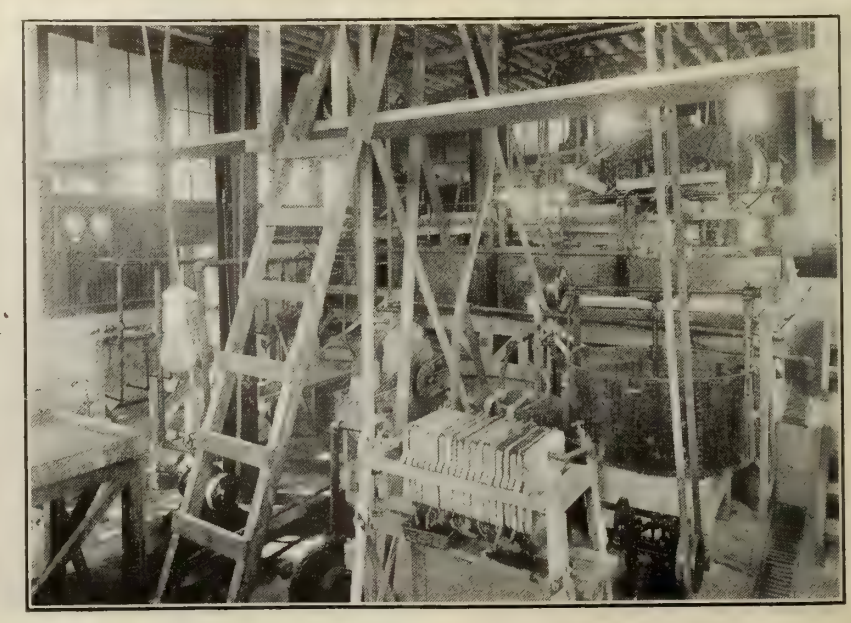
Enthusiastically Supported by District Business Men—Ideal Locality for Mining School—Experimental Plant Capable of Handling One and One-Half Tons in Eight Hours

THE EXISTENCE of a successful technical school in a town the size of Haileybury is to be attributed to the enthusiasm of the people of the community and especially of the high school board under the chairmanship of George T. Smith. It has had the liberal support financially and otherwise of the Department of Education. Our aim has been to combine training for expert positions in the mines and metallurgical laboratories of Northern Ontario with a thorough education in English, history, civics, and mathematics. The number of important technical positions filled by former students bears witness to the success of the school in its technical training.

Two activities not dealt with in the body of this article may here be mentioned: first, special short courses, and second, research work. Every session a number of prospectors and others enter to take up work in some special subject such as mineralogy or drafting. During the years 1919-20 and 21, upwards of thirty returned soldiers obtained special vocational training in the school, through the co operation of the Department of Soldiers' Civil Re-establishment and the Ontario Soldiers' Aid Commission. Milling, assaying, chemistry, and mechanical drawing were the subjects mostly taken by these men. During the past two years the Ontario Department of Mines has conducted a short course for prospectors which has been largely attended. As to research, a series of tests made during 1919-20 for the American Cyanamide Co., of Niagara Falls has resulted in the use of the cyanide made by this Canadian company in many mills instead of the imported article. Tests have also been made for certain mining companies leading to improved methods of ore treatment. In these tests the senior students assist, thus acquiring not only practice in the operation of the mill machinery, but an insight into the exact quantitative methods that characterize research work. The unique equipment of the mill, and the ease with which it may be adapted to various methods of ore-treatment suggest that the school might well be used frequently for such tests.

School Facilities

The Haileybury high school was built with the intention of serving the needs of the three towns, New Liskeard, Haileybury, and Cobalt. Owing to the location of Haileybury midway between the other two towns it was chosen as the school site, and as the most convenient means of accommodating the majority of the students in this district. The building is a three story brick structure, and was opened in 1910 with a total attendance of 11 students. The register has, since that time, shown a steady and encouraging growth; the enrolment for 1921-22 being 107 boys and 94 girls, a total of 201, and arrangements are being made for additional rooms in order that the further increase, anticipated for the next term, may be provided for. Students are in daily attendance from Cobalt and New Liskeard and the surrounding districts, some traveling 15 and 25 miles. Those not living in Haileybury find conveyance on the Nipissing Central Railway, an electric line, connecting the three towns, and on the Temiskaming and Northern Ontario Railroad; both of these lines giving students special low traveling rates. The school is widely known in the North, and is patronized by students from as far north as Cochrane and Schumacher and south from Sudbury and Parry Sound.



The mining department was introduced in 1921 with two primary objects: (1) as a means of giving boys desirous of following mining or kindred professions a practical and technical foundation upon which to start their life work; (2) as a preparatory course for those wishing to enter Queen's School of Mines and qualify as professional engineers. The classes were held in the high school building till 1917 when the mining building was erected.

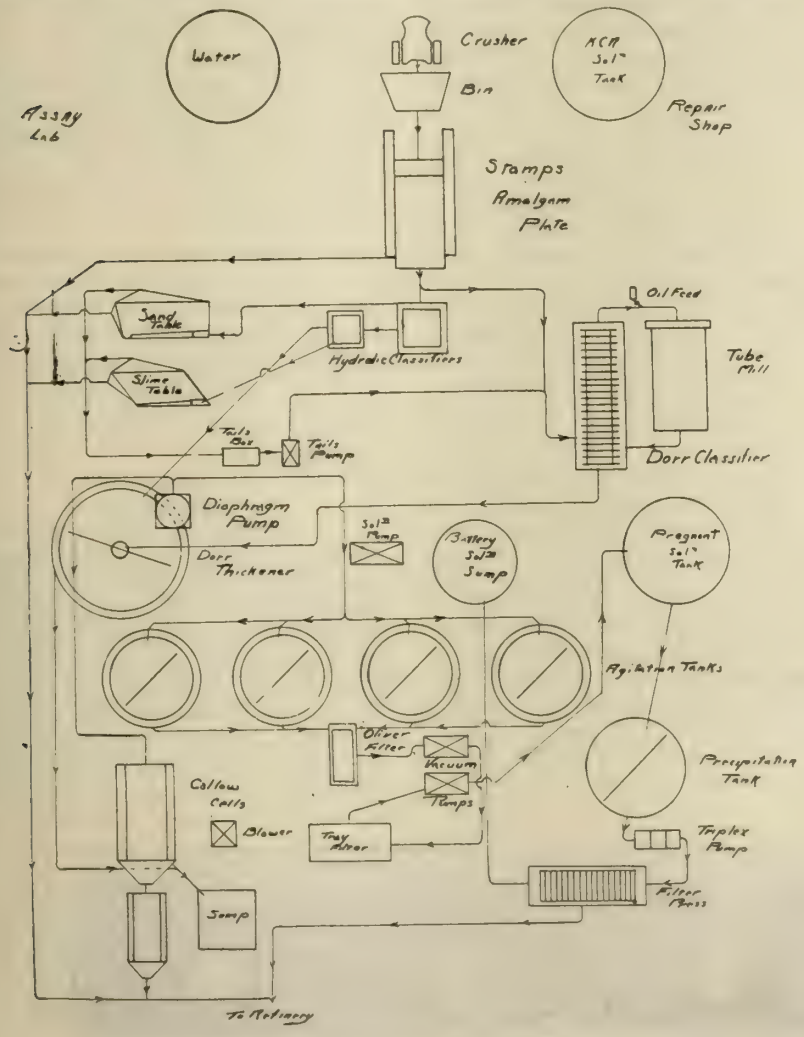
Ideal Location

As a location for this course, Haileybury could almost be said to be ideal. The silver producing camp of Cobalt, five miles to the south, gives the student an ample opportunity of acquiring a practical knowledge of mining, milling, smelting and refining methods, machine shop practice, labor conditions in mining, power production and distribution, etc. In the immediate vicinity of Haileybury is to be found a diversity of geological formations, probably unexcelled on the continent This gives the student an opportunity of specializing in the knowledge of geology. The closeness of, and opportunities offered by, the growing gold districts of the north give an added impetus to this work. The mining course being run in conjunction with the regular high school work affords the students the many benefits to be derived from the latter. He meets in friendly rivalry his fellows of the academic courses on the athletic field or in the literary society, which checks any tendency to become too narrowly specialized.

The above facts were early recognized by Mr. W. A. Wilson, principal from the opening of the school till 1919, and it is largely through his efforts that the course was introduced and brought to its present state of efficiency. Local mining men were not slow to see the advantages of educating the boys of the district along mining lines and gave the department their full support. It was made quite plain from the first that a building separate from the high school would be necessary to carry on the special work of this course and accordingly in 1917 the present mining build-

Through the courtesy of W. H. Tuke, principal of the school, the material was compiled by two students, Frank McLellan and Wm. Beaton.

General view of the mining department at Haileybury School.



ing or "Mill" was erected. Its construction and successful operation are in no small part due to the interest taken by the various mining companies of Cobalt. A large amount of the equipment was donated by these and the designing of the plant and installation of the machinery was closely supervised by Messrs. F. D. Reid, J. J. Denny, and M. F. Fairlie, of the Advisory Technical Committee.

Plant Facilities

A visitor can not but be impressed by the up-to-date appearance of the plant, and the completeness with which every detail has been worked out to secure efficiency of operation and economy of space. Practically all the available room has been utilized for the machinery, yet nothing has been crowded. Every part is accessible and illuminated in the daytime by an abundance of natural light. All pulleys, belts, and shafts, have been placed in such a manner as to incur the least possibility of accidents, and at the same time make them most convenient for repairs and lubrication. All launders are systematically arranged and are open throughout their entire length for inspection.

The plant is capable of handling one and one-half tons of ore per eight-hour shift. The flexible and easy manner in which it can be converted from one process to another and adapted to treat almost any ore is a distinct credit to the designers and forms the most noteworthy feature of the equipment. Situated in the midst of the gold and silver mining districts, special attention was given to these phases of metallurgy in designing the building; but this does not detract from its value in teaching the underlying principles of milling methods used in connection with other ores.

The plant equipment includes: one 8 x 10 Sturtevant roll jaw crusher, presented by Seneca Superior Mining Co. of Cobalt, stamp battery of three 175-lb. stamps, donated by Col. Leonard of Coniagas Mines; one 4in. x 23 in. amalgamating plate; two-compartment hydraulic classifier of wooden construction, one 50 in. x 24 in. Wilfley sands table, one 50 in. x 27 in. Reid-Duster slimes table. The head motion for these tables was made by the Wabi Iron Works of New Liskeard, while the deck for the slimes table was donated by Mr. F. D. Reid of Cobalt. A model C Simplex-Dorr classifier operates in closed circuit with a 43 in. x 33 in. ball mill for fine grinding. The ball mill is also a product of the Wabi Iron Works; it has a normal capacity of one ton per eight hours and can be used for either wet or dry grinding.

Flow sheet of Haileybury School of Mines.

De-watering and Flotation

The first step in the de-watering process is a 72 in. by 45 in. Dorr Thickener, the product from which is removed by a diaphragm pump. The latter can discharge into a 48 in. x 36 in. pan filter, or an Oliver 7 in. x 36 in. continuous rotary filter, or into the cyanide agitation tanks, or into the flotation tanks. The ball mills, tables, pump, and thickener, are all operated by a 15 h. p. G. E. induction pump. The cyaniding equipment consists of four 24 in. x 48 in. agitation tanks, one 42 in. x 24 in. pregnant solution tank; one barren solution tank 60 in. x 43 in. and a precipitation tank 48 in. x 24 in. All tanks are of steel construction, built by the Wabi Iron Works.

The precipitation press is a 12 in. x 12 in. nine-leaf filter of the Merrill type. A ¾ in. x 2½ in. triplex pump is used for forcing the solution through the press.

The flotation department consists of a Callow pneumatic machine capable of handling 1 ton per eight hours. Air is supplied by a No. 20 Connersville blower at 5½ lbs. pressure; this blower also supplies the air necessary for aeration in the cyanide work. All of the machinery in the cyaniding and flotation sections is operated by a motor of the same type as that used in the grinding and table sections. In addition to the above mentioned machinery there is a large amount of smaller apparatus used in making preliminary tests on ores and for demonstrating the fundamental processes in metallurgy. These include a small Callow flotation machine, a wheel and roll agitator, miniature jigs, etc.

Power Transmission

All of the main and counter-shaft bearings are of the hanger type, supplied by the Dodge Manufacturing Co., through their Cobalt representatives, the Northern Canada Supply Co. Shafting, belting, valves, piping, etc., were all generously donated by various supply houses at Cobalt.

Electricity is used for all power purposes at a potential of 220 volts. The current is supplied by the Northern Ontario Light and Power Co. All electrical equipment is of standard approved type and so installed as to leave practically no danger to students. Water for milling purposes is supplied by a 500-gallon tank in the attic. It is arranged with an automatic float so that a constant head is assured. The primary source is the water-works system of Haileybury from which the supply is received free of charge. The assay department is provided with a set of Sturtevant rolls, a Braun pulverizer, buckboards, samplers, etc., and includes one pot and two muffle furnaces along with necessary flux and button balances.

The school has two chemical laboratories located in the mining building, besides the general laboratories in the

main building. One of the special laboratories is used for the junior students in general chemistry, the other and smaller room for the senior classes in qualitative and quantitative analysis. A supply room is conveniently located between the two laboratories. The senior room has a large fume chamber with sliding glass front sections, hydrogen sulphide generator, water distilling apparatus, electric drying oven, and electric hotplates of various capacities. Half the upper floor of the building is occupied by a room at present used for mechanical drawing. The accommodations for this purpose are of a temporary character, and it is hoped in the near future to have up-to-date equipment of tables installed. Provision is made for blueprinting. Equipment for surveying includes a transit, dumpy level, clinometer, planimeter, rods, chains, tapes, compasses, etc.

Other Departments

A limited equipment for wood and metal working has been installed. The former includes a number of tables and small tools, two lathes, and an Elliott wood worker. The latter consists chiefly of repair apparatus, a forge, pipe stock, dies, wrenches, etc. Extension of this part of the work is hampered by lack of room. There is not probably sufficient demand to justify the installation of complete wood-working or machine shop equipment, but additional pieces by which the student could be taught the basic operations, and especially what is needed for repair work in mines and mills could be used to advantage.

The course is at present planned for the average student to cover three years for a junior, or four years for a senior diploma. Completion of the latter permits the student, by special arrangement to enter the Queen's University School of Mines. Throughout the term English, history and mathematics are studied. Trigonometry is begun in the second year to prepare the student for the work in surveying. Physics, chemistry, geology and mineralogy form the foundation on which the more strictly technical subjects, milling and assaying, are built up.

It is felt that no intelligent use can be made of machinery or mechanical processes without a thorough understanding on the one hand of the scientific reasons underlying these processes, and on the other, of the materials with which the miner and metallurgist has to deal. In this connection some of the most important lessons are learned on the numerous field trips, which are made when the weather permits in autumn and spring. From these the geological structures and processes are studied both overground and underground, while in the latter location study is also made of the method of developing ore bodies. Most of the students supplement the knowledge gained in this way by working in the holidays either in the

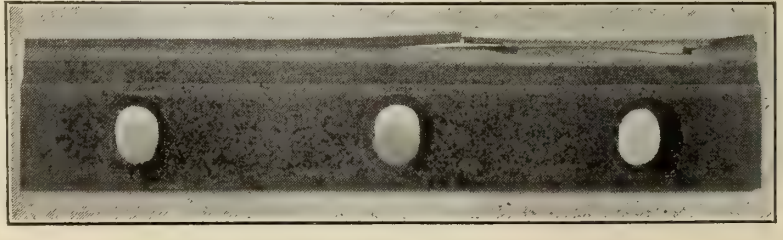
GRINDING HIGH SPEED STEEL

DURING the past few years, several very hard, dense steel alloys have been developed particularly for use in reamer blades, cutters, and tools. Probably most of the readers are familiar with the difficulties encountered in grinding these alloys such as checking, cracking, and distortion of the steel. We shall outline briefly the experience of one plant in overcoming these difficulties.

The steel in question was a high speed tungsten alloy. It was extremely hard and dense and very sensitive to rigid temperature changes such as might occur during grinding, if special care were not used. This steel was in the form of reamer blades 1 in. thick. The grinding was a very delicate proposition and required extreme accuracy.

After the reamers had been set up, they were ground cylindrically on a 14 in. x 96 in. plain grinder to the correct taper, leaving 0.020 in. of surplus stock as measured diametrically to allow for lipping the cutting edge. This lipping consisted of grinding a concaved flute along the edge of the reamer blade about ¼ in. to ⅜ in. wide and 1-16 in. deep. For this purpose a portable electric grinding machine was bolted to a steel arm projecting from the safety hood of the machine, so arranged that the spindle of this portable machine was at right angles to the table traverse. Wheels 3 x ⅜ x ⅜ in., grain 3846 grade K, alundum vitrified with a rounded face, were used. The electric grinding machine was then dismounted and the reamer finish ground cylindrically to as nearly perfect size as possible. The limits as measured diametrically were plus 0.00025, minus 0.000.

The next operation was that of backing off the blades and here the real difficulty arose. It was done in the same machine with wheels 14 in. x 1 in. x 5 in., which happened to be the only size available at the time. A number of different grains and grades were tried with every possible combination of feed, table speed, and dressing available on the machine, but the blades would invariably burn black and develop fine cracks after the table had traversed only half of the reamer length. This happened when grinding both wet and dry; in fact, it was found impossible to grind the material wet under any conditions. A Huntingdon dresser was used to open up the face of the wheel with little or no improvement in the results. A feed as light as 0.00025 in. per traverse caused bad burning. The blades would develop fine cracks which would gradually open up until pieces would break off altogether. (See cut.) Sometimes, after burning, cracks could not be seen, but the blade would break down while being used. The wheel face did not show any signs of loading or glazing and it occurred to the operator that perhaps he was not really removing stock, but rather that the wheel was simply rubbing over the steel and generating the heat which caused burning. Therefore, it seemed a question of forcing the wheel to remove the material.



A fresh start was made and the wheel (Norton 3846-I vitrified) dressed with a Huntington dresser to a very coarse face. It was then fed into the work 0.002 in. and the reamer traversed by hand as rapidly as possible. The grinding was done dry. The result was very encouraging. Not a sign of burning appeared although we had taken a much heavier cut than before. The step was repeated with the same result. Apparently the problem was solved and all of the reamers were backed off in this way in a very short time and with absolutely no burning. Of course, the wheel showed some wear to each traverse, but this was negligible as lighter cuts could be taken on the final traverses of each blade to avoid the excessive wheel wear. An extremely fast table traverse was the real factor in eliminating the burning of the steel. This company has since changed to the use of a 3824 grade H Aldundum vitrified wheel for the backing off work.

The reamer blades were backed off to a very narrow land and afterwards honed. By mounting the whole finished reamer in a lathe and trying the blades at intervals with a bar of copper mounted in the tool post, the rubbing or honing of the edges to insure equal working capacity of the blades was readily accomplished.

From the Norton Records.

ERRATA

In the March 30 issue appeared an article on "Micrometers Make Standardization Possible." The following corrections should be noted:—page 22, third column, line 9 should read, "is 1-1,000 in. or 10-10,000 in. the difference." On page 27, third column and 16th line, should read "scale and the 1, 2, 3, 4, 5, 6, etc. lines on the Vernier of .001 in., .002 in., .003 in., .004 in. etc., respectively."

Effect of grinding with improper grade of wheel.

Gear Construction Material and Application

End to End Keys Best for Rawhide Pinions—Scrap Should Not be Used in Making Gears—Bronze Most Suitable for Worm Gears—Stamped Blanks for Light Work

By CHESTER B. HAMILTON, Jr., B.A.Sc.

IN CONSIDERING the production and application of toothed gearing let us first take up the material from which gears can be manufactured. Gears can be made from material of non-metallic or metallic character. The latter may be non-ferrous or ferrous, and the ferrous material may be cast iron or steel.

Non-metallic gears are generally used to eliminate noise. This is their only point of superiority over metal gears. All gears were originally made of wood, but long after iron became common material for machine parts, wooden cogs in mortices were retained for one of a pair of gears where quiet operation was required.

Rawhide is much used as a material for pinions. After special treatment it is cut into discs and glued into cylindrical blocks which are dried under compression. These blocks are usually sold to the gear makers in fifteen or eighteen inch lengths, which can be cut off as desired. Good practice calls for the supporting of the rawhide laminations between metal flanges, on the ends, the whole being held together by long rivets.

After assembling and riveting, the composite blank is then turned all over and the teeth cut clear through the flanges the same as any other pinion. Rawhide pinions should always be driven by keys, never set screws, as the latter apply the torque all at one end and are liable to loosen the rivets. The flanges are usually brass and the cutting speed of both brass and rawhide is high. Steel flanges reduce the cutting speed of the whole job to nearly the speed for steel, with no compensating advantages.

It is customary to save old gear cutters that are nearly worn out for use on rawhide pinions for two reasons. The duty is lighter, and they do not break but can be worn out to the end. The spaces between the cutter teeth are greater due to repeated grinding, and the rawhide chips do not pack in and jam the cutter, as is sometimes the case with new ones.

Oil and water, and excessive heat are all more or less injurious to rawhide pinions. High grade well cured rawhide is not as susceptible to injury as inferior material. Imperfectly cured hide can be detected by its bad smell when machining. The best hide is from the East Indian water buffalo. This is considerably superior to the ordinary beef hide, though more expensive.

Fibre is used to some extent for gears, but it is not generally considered a first class material. It is applicable for light duty. Its special virtue is that it is immune to injury from oil, and can therefore replace rawhide to advantage in some instances. In many places where fibre was formerly used, modern practice calls for a higher quality of metal gears, giving silence by reason of accurate helical generated teeth. There are three commercial classes of fibre, distinguished by their colors, grey, red, and black. Only the grey is fit at all for gears. The black is very weak, short-fibred and crumbly. The red is strong, but is loaded with a mineral filler which is very hard on tools.

Raw cotton, compressed to a solid mass by enormous pressure, is used very successfully for pinion blanks. This is not general however, the process being controlled by the patents of one firm, who do not co-operate with the gear industry at large in a way to promote the use of the material. The pinions are very strong and durable under almost all conditions.

Bakelite-micarta is the most modern material for non-metallic silent pinions. Bakelite is a condensation product of carbolic acid and formaldehyde. It occurs in three allotropic forms, which might be described as resembling a syrup, a gum and amber. Heat causes the changes from one form to the next, which changes are not reversible.

The fibrous, strength-giving element of the pinions is cotton duck, which is impregnated with the material in its first form and dried, cut into sheets, usually thirty by thirty-six inches, and stacked up in a hydraulic press. In this it is pressed and heated under pressure converting it into solid slabs of certain standard thicknesses, sheets of metal having been previously inserted at the required points of subdivision. The Bakelite is transformed successively to its second, and then third allotropic form, and finally fills all the interstices of the cotton duck with a rigid binder, of artificial amber. This is a first class gear material.

Pinion blanks are cut from the slabs with an ordinary patternmaker's narrow blade band saw. If the face of the pinion is greater than the thickness of any slab available, it may be built up by combining discs of suitable thickness and riveting the whole. It has the advantage over rawhide that flanges are not required, and also that it is not affected by heat, oil or water. In fact, the bakelite itself is unaffected by any reagent except boiling caustic.

Non-Ferrous Gears

The non-ferrous metallic gears can in general be classed under the term "bronze" where high duty is required, "brass" where the duty is light and speed of cutting or ease of working is the point, and thirdly, various, often nameless, alloys of low melting point which are used in the die casting process. This process has made great advances in recent years, both mechanically, and metals can now be die cast which have quite considerable strength, such as some varieties of brasses.

Generally speaking, brass, whether die or sand cast, or rolled, is not considered a high grade gear material. In fact, for a job of any size it is literally not worth its price, for a good bronze gear of equal strength would be sufficiently smaller to be cheaper. This of course does not apply to small gears where load carried and cost of material are almost negligible, and a metal is wanted that will cut at high speed, take a fine finish and not dull the tools, so that the close limits of accuracy used on small work can be maintained. Brass also sometimes replaces cast iron on account of its non-rusting qualities, especially for worm gears.

Good bronze, of suitable formula and well made, is a very high grade gear material. The so-called navy bronze of formula 88 copper, 10 tin, and 2 zinc, has been a standard for years, and owes doubtless part of its success to the fact that any intelligent brass founder can make it, which is more than can be said of some of the complicated special formulae in use. For worm wheels, where the action is largely sliding, the zinc can, if the unit pressures are not too high, be replaced with lead, which acts as a natural lubricant. This softens and weakens the metal a little. Phosphor bronze is deservedly popular, but requires more care.

There are at least two easy ways of spoiling it, which are common in small foundries. One is by the use of zinc, which will not alloy satisfactorily with phosphorus, or in the presence of phosphorus. The other is due to failure to alloy metallic phosphorus with the remainder of the charge and allowing it to burn off at the surface. In this case the phosphorus practically disappears, and though it does some good in the going, as a purge or cleanser, the result is not phosphor bronze. The latter trouble can be eliminated by using in the charge phosphor-tin alloy of known composition instead of metallic

phosphorus. No scrap, only virgin metal, should be used for gears.

For Heavy Work

For such very heavy duty work as the worm gears in rear axles of motor trucks only the very best bronze is used. Some makers have special formulae, sometimes of a secret, or proprietary nature for which great claims are made. The heat treatment of bronze has developed some importance recently in this connection, for the refinement of grain and increase of strength and durability. Aluminum alloys have not so far been found suitable for gear material, though it is said that an aluminum bronze has recently been developed for which great claims are made. As with steel, the microscopic study of bronze is leading to new developments, and micrographic metallurgy is a most fascinating field.

Iron and Steel

The great majority of gears are of iron or steel, in some form or grade. Commercially pure iron, that is wrought iron or extra mild steel, is not a suitable gear material, as it is too soft to wear, and even if case hardened, lacks the rigidity necessary for the core to support the case. Further, there must be carbon enough in the steel to let it be cut cleanly and freely. Too mild a steel drags and tears, making a good finish and accuracy impossible.

Cast iron is at the opposite extreme, so far as carbon content is concerned, and perhaps should be concentrated first, as it is the oldest metallic gear material. The best cast iron for gears is of an intermediate grade. Hard white iron in which all the carbon is in the combined state is too difficult to machine, and is brittle. Very soft grey iron with an excess of graphitic carbon does not wear well. Low silica irons are to be avoided on account of their chill hardening propensities. An important item in castings for spoked gears is the selection of a mixture that will give low shrinkage, as a high co-efficient of contraction will surely lead to trouble from cracked arms and to unrelieved internal stresses.

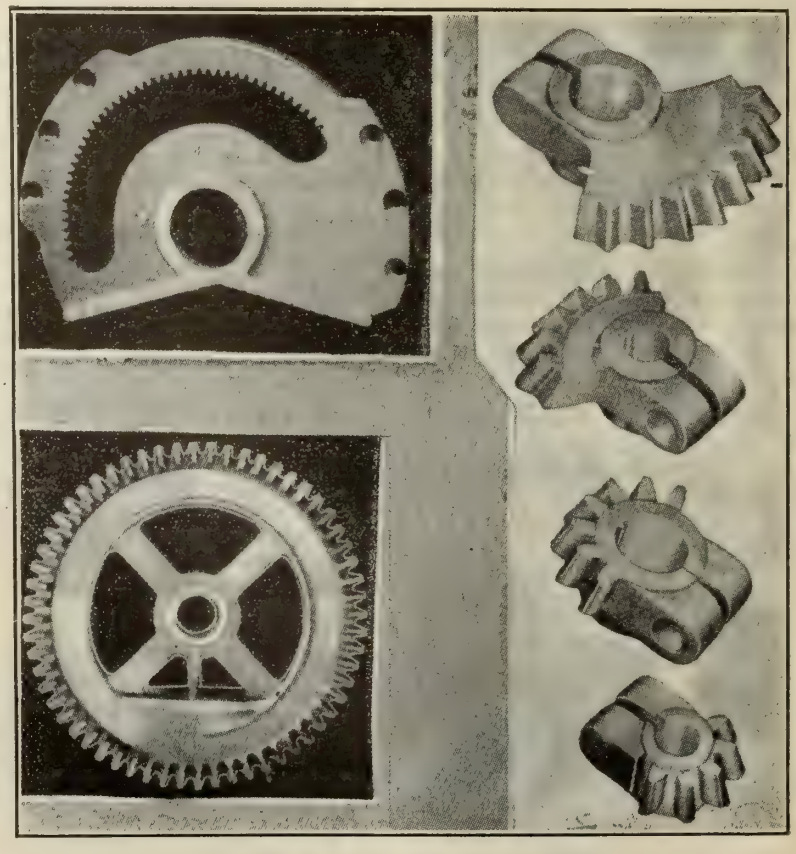
Semi-steel had better been named "semi-cast iron," for it is not steel, but cast iron enriched and strengthened by an admixture of steel. The percentage varies, up to thirty per cent. steel being added in some cases, though it is usually much lower. In all cases where a considerable percentage is added, special attention must be paid to the chemical composition of the mixture, or bad results such as metal hard to machine, will follow. Semi-steel of low percentage steel can be made in the ladle by dissolving steel turnings in the liquid iron. This lowers the temperature considerably, and can only be used for castings of such form that high fluidity is not essential.

As there is an upper limit to the temperature at which the iron can be drawn from the cupola, so there is a corresponding limit to the percentage of turnings which can be added. This will vary with different foundries, different mixtures, and also vary with the class of casting to be poured. Thermit has been used in the mixing ladle with this method of adding steel, to maintain the temperature of the metal by replacing the heat absorbed by the fusion of the steel. The Thermit in a specially constructed can is fitted to the end of a rod and immersed in the liquid metal. The high percentage semi-steels require a different method of adding the steel. In this case steel scrap is charged with the pig and scrap iron into the cupola, and on melting comes down with the iron and combines with it in a liquid condition before tapping.

Steel castings for gears are usually made by the acid open hearth process. Basic open hearth is not much used for this purpose. Bessemer converter steel is also secondary to the open hearth on account of its liability to blow holes and kindred gaseous defects. A variation of the Bessemer, known as the Tropenas converter system, was formerly used to a considerable extent on account of the high fluidity of the metal produced, which was a great advantage in filling thin sections and intricate castings.

Crucible steel is not used for gears on account of the expense. The electric furnace is the most modern producer of high grade steel, in both the carbon and various alloy steels. This material is of superior quality, due to the better control of the process both chemically and physically, which is possible in an electric furnace. It has heretofore been too expensive to compete with any but the crucible, but of late improvements in the electric furnace, the high price of coke, and the development of hydro electric power on a large scale have placed this process in close competition with the open hearth.

Steel castings are generally much rougher and not so true to pattern as iron castings. Steel gears with moulded teeth are therefore found only in the largest sizes. Steel castings require to be thoroughly annealed after removal from the sand before they are fit to be machined as gears.



The modern alloy steels, involving the use of nickel, chromium, vanadium, etc., are used to some extent in steel castings, especially in the product of the electric furnace, but the bulk of the alloy steel gears are of rolled or forged material.

Wrought material for gears may be classified according to the process by which it is produced, as follows:—Hammer forgings, usually made under a steam hammer or hydraulic forging press from the billet or bar, are used where a comparatively small number of like pieces are wanted, and for large pieces, beyond the capacity of a drop hammer.

Drop forgings are made under a steam or board drop hammer with half dies in place of the two plane faces of hammer and anvil. As these dies are expensive, the process is adapted only to repetition work. The quality of the work produced is generally good, and, if due regard is paid to the finishing temperature, the material is improved by the mechanical working.

Stampings are made from rolled sheet or plate under drop hammers or crank

How Science is Breaking New Trails in Industry

Alcohol to Compete With Gasoline—New Uses for Water and Electricity—Chemical Treatment of Cotton Against Fire Saves Millions of Dollars—Waste Fruits Provide Valuable By-Products

SUPPLEMENTING freight and passenger traffic on North American railroads and highways last year, a thousand airplanes were employed commercially in the United States and Canada, and these machines flew 6,000,000 miles, carrying 225,000 passengers and hundreds of tons of package freight. This advance in commercial aeronautical enterprise has taken place without the assistance or protection of law, in credits, insurance and the like. Its future is a challenge to the imagination. Not long ago an English business man chartered an airplane in Paris and for twenty-three days flew around Europe, touching at Brussels, Berlin, Warsaw, Trieste, Venice and many other cities. He is reported to have accomplished his business in one-tenth of the time that he would have consumed in going by train.

In view of the decreasing supply of gasoline as a motor fuel, according to Floyd W. Parsons in the Saturday Evening Post, laboratories are now at work producing alcohol that is equal to gasoline in providing mechanical energy, at the rate of from twenty to forty gallons per ton of parched shrubs or roots. The Germans get most of their power fuel from potatoes, and just as soon as business becomes normal and gasoline prices again advance, motor fuel from blackstrap molasses and from grain and fruits will be in the market competing with gasoline.

When the price of oil again gets as high as $1.50 a barrel, we are assured, the shale-oil industry will again awaken and the result will be another competitor to check any runaway market which may develop in oil. Shale-bearing rock is present in this country and throughout the world in even greater quantities than coal. Also ways are being devised to "break down" radium and to apply the same treatment to other elements which are found in comparative abundance throughout the world. For instance, the energy latent in metallic uranium, which is gradually given off during slow disintegration, is so enormous that the amount liberated by the complete disintegration of 100 pounds of the metal is approximately equivalent to that obtained by burning 18,500 tons of coal.

Science, the bed-rock of business, is still working to produce cold light like that emanating from the little firefly, and its production will affect finance and industry enormously. This is cited as one of many inventions which will directly affect our lives and businesses. We are to have new types of fuel-saving boilers, in which great economies will be effected, because instead of having to heat a large amount of water in a cumbersome boiler only one or two gallons will have to be heated at a time. There is promise of the successful development of hydrogen-gas motors propelled entirely by water. In such motors the water will be used over and over again, and, of course, should they be successful, there will be no transmission system necessary.

One inventor connected with a famous institution has already cooked all kinds of food with his solar cookstove. Every method of cooking except frying has been successfully tried on this stove, which consists of a concave, parabolic, cylinder reflector, through which runs a tube of ordinary cylinder oil to absorb heat from the reflector and apply it to the cooking compartment. Carefully adjusted insulation insures the retention of the heat in the oil overnight. A float device automatically regulates the cooking temperatures, while a simple clockwork mechanism keeps the reflectors facing the sun.

Abroad they have recently been experimenting with schemes for transmitting power by wave pulsations carried through pipes and conducted by a fluid, preferably water. This will be a sixth way of transmitting power, the other five being by steam, direct mechanical, hydraulic method, electricity and compressed air. In this new plan the power is communicated to water in one end of a conducting pipe, and the resulting waves carry it the full distance of the pipe's length. At present waves 120 feet in length are being sent through a one-inch pipe a distance of one mile to operate a riveting machine which delivers 2,400 blows a minute. The waves transmitting the power travel at the speed of sound in water. It is asserted that the pipe can be tapped at wave lengths or half wave lengths, and so may be made to serve a number of machines. Only the other day a Western druggist discovered a way of treating baled cotton so as to render it fire-proof. As a result, we read, the railroads now consent to carry this chemically treated cotton on open flat cars, and insurance companies are reducing their rates on these fireproofed bales as much as 90 per cent. No product of American farms is more dependent on bank credit than cotton, and the obtaining of credit by growers and shippers has been hampered because of the serious losses resulting from the chronic rotting of the staple during storage and shipment. The liquid treatment of the bales does not injure the cotton, but, on the other hand, does eliminate the former losses of from 80 to 400 pounds a bale due to rot.

Upon actual demonstration treated cotton showed no signs of fire damage after being transported 900 miles on flat cars next to the locomotive, although the bales were buried in cinders after the trip. This development will release some 40,000 box cars, formerly needed for moving the cotton crop, for the transportation of grain and other farm products.

In the farming and fruit-growing industry, we are told that, whereas the California and Florida fruit growers a short time ago were delighted to get $5 a ton for their cull oranges and lemons, this waste now is made to yield annually about 1,500,000 pounds of citric acid, 500,000 pounds of citrate of lime and 50,000 pounds of lemon oil. Our tomato-seed waste is being converted into an edible oil of high quality, as well as into a meal suitable for feeding cattle, hogs and chickens; and useless apples, even those that are intensely acid, are being made to yield calcium malate, the source of malic acid. The development of this latter process in Nova Scotia promises to result in the establishment of a new industry of considerable proportions.

NEW TURRET LATHE

The hexagon turret lathe is one of the most familiar of machine tools; in fact, it is so familiar that the possibility of radical changes in its design is not generally entertained. A British firm has, however, completed in its experimental shop an entirely new type of hexagon turret lathe. The improvements were suggested to the makers by the effects of heavy war service on ordinary types; and it represents a successful effort to remove the possibilities of damage and wear under the most strenuous conditions. One of the main features of the new machine is the covering of the scraped bed slides completely by cast iron guards. The covers fit closely to the slides and thus prevent dirt and chips entering between the surfaces in contact. Another chief feature of the machine is the way in which all possible points of danger are guarded against. All the actual machine operations are performed at the highest permissible speed, and the skill of the designers has been specially directed to increasing the speed at which non-productive movements are effected. Still another feature to which great importance is attached is the fact that the spindle is supported in single track roller bearings. Exhaustive experiments were made to prove that these bearings would stand the strenuous conditions imposed by continuous fast production. The machine is capable of turning lengths up to 30 in. at one setting and of taking bars up to 2 in. in diameter.

Practical Ideas from Practical Men

HIGH SPEED STEEL AND SOME OF ITS USES

By I. N. B.

There is no advantage in using high speed drills in automatic screw machines, where the cutting speed of the drill does not exceed 40 ft. per min. This refers to such machines as have no devices to increase the speed of the drills. For instance, a piece being machined 2 in. in dia., at 80 ft. per min., the stock would revolve at 153 r.p.m. The cutting speed of the drill is only 30 ft. per min., so that a carbon drill will answer as well as one of high speed steel.

As a general rule there is little to be gained by using high speed drills below ¼ in. dia. in ordinary drill presses, as they are not designed to operate at the necessary high speeds. To obtain an 80 ft. cutting speed for a ¼ in. drill the spindle would have to run at 1222 r.p.m. and few ordinary drilling machines will operate at such speed without excessive vibration.

Frequently high speed chasers are ordered for dies where the cutting speed seldom exceeds 25 ft. per min. Better results are often obtainable with the carbon steels. Owing to the high temperature required in heat treating the high speed steels, there is the possibility of damaging the points of the threads, and, due to the deoxidizing that takes place, surfaces must be ground to bring back the keen cutting surfaces, a condition that is very difficult in taps and dies.

DIES AND FORMING TOOLS IN AUTOMATICS

In using dies on automatics it should be remembered that the cutting of comparatively fine threads is equivalent to turning with coarse feeds, therefore the time allowed for cutting the thread should be equal to the time for the longest turning operation. There is nothing gained in getting the die on and off in the shortest time and then waiting for the completion of another operation.

The improper grinding of dies is another source of trouble. If the head is not true with the pitch the die will not follow true and each land will have to cut a path for itself instead of following in a true head. Hence the thread will be rough and irregular. A thread slightly less than full is easier to cut and the loss in strength is less than 5 per cent., and the thread is 50 per cent. easier to cut.

Forming tools designed to cut irregular shapes are given certain angle for rake and clearance so that any variation from design will make a difference in the finished work. Hence, all forming tools should be ground and set to gauge.

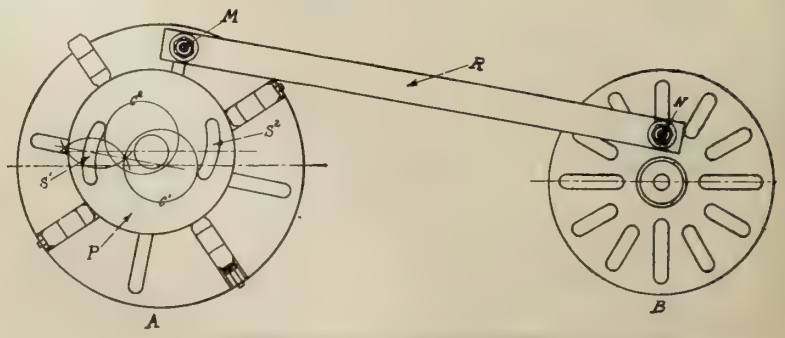
To attain the maximum efficiency in the performance of any machining operation, there are two general factors to be considered. Means must be provided for cutting the metal at a satisfactory rate, and care must be taken to reduce the idle time to the minimum. It is obvious that any material gains in effective cost reduction must result from a systematic application of past experience rather than mere assumption.

A PROBLEM IN TESTING

By G. Blake

The writer is engaged in the manufacture of small lathes, and until recently had been using a test bar for testing the alignment of the bearings with the bed. The method of testing is as follows: the test bar is inserted in the bearings and locked by the screws in the bearing caps, a block with a vee edge to correspond to the shears of the bed (front side) is used with a dial indicating gauge. The writer previously allowed an error of .002 in. in 24 in. the test bar projecting from the front bearing by about 28 in. The inspector set his gauge at zero at the headstock end of the test bar and passed the lathe if it did not show more than .002 in. at the tailstock end. This test was applied both to top and side of the bar.

A question was raised as to the amount of deflection of the test bar and the writer ventured the opinion off hand that he did not think it would amount to more than .0015 in. on the 28 in. length, but on referring to the text book and using formula given, it proved that the deflection was .008. This surprised the writer and consequently upset all our calculating. When the bar showed zero at the headstock end and .002 in. high on the top at the tailstock end at 28 in. overhang of the bar, it really was .010 in. high at the end instead of being only .002 in., as shown on the indicator, the deflection accounting for the .008 in.



Next by taking a test at 12 in. overhang the deflection was less than .001 in. Now to prove if the deflection was actually .008 in. the test bar was again inserted at 28 in. overhang, the bearings tightened up so that the bar was rigid. The gauge showed at zero at the extreme end of the bar on the side test, that is the lathe in its ordinary position. The lathe was now turned on its side 90 degrees, the gauge again tried up against the bar, when it showed that the deflection was slightly more than .008 in. It actually registered .0105 in., showing that another factor had to be taken into account and that was the pressure of the spring in the dial gauge. A test was made on this and it showed that the pressure of the spring registered a deflection of .0025 in. on the test bar at 28 in. overhang; the diameter of the bar was 1¼ in. and it was made from ordinary good mild steel approximately 35 to 40 tons tensile.

We had the records filed away for future reference and decided that in future all our tests would be made on a bar projecting 12 in. from the headstock as the deflection on this length was under .001 in. All this goes to show how easily one can be led astray until actual experiments are carried out and very carefully checked.

CAM CUTTING KINK

By J. H. R.

An interesting method of cutting two diametrically opposed eccentric cam slots in a large disc is shown in the accompanying sketch. The slots S had an approximate length of 5 in. and a width of 1¼ in., the movement of the disc when in position on the machine, giving a radial travel to a pair of jaws of about ⅞ in. After the location of the slots had been laid out on the plate the metal was rough drilled to the boundary lines. The disc was then placed in the chuck of a large lathe, as shown at the left, and a bar clamped at the rear to act as an oscillating lever for smoothing out the slots. However, after a few strokes by the "strong arm" method, it was noticed that the face plate of an adjacent small lathe was just about in line with the chuck of the other, so the arrangement shown here was soon rig-

Cutting cam by means of two lathes.

ged up, with good results. The studs M and N were made of the desired length and connected by the bar R. The stroke was regulated by adjustment of the stud N. Starting up the small lathe B gave the necessary movement to the lathe chuck A.

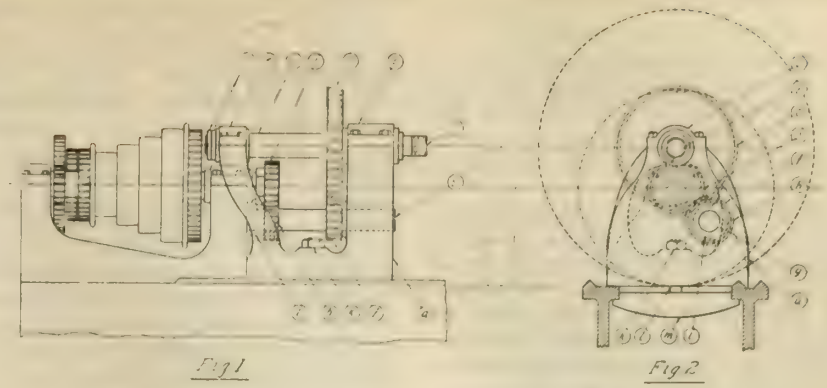
GRINDING BILLETS AND BARS

By R. H. Cannon

All of the high speed and tool steel billets at a large billet manufacturing plant are cleaned by grinding. Wheels 14 in. x 2 in. x 1¼ in. are used on swing frame machines. All of the scale is ground from the rough billets first and then the flaws and cracks are completely ground out. The billets weigh between 100 and 400 pounds. From time to time objections were raised about the grinding wheel cost per ton of billets ground and attempts made to reduce this by increasing the hardness of the wheel. This resulted finally in the adoption of a grade W wheel. Wheel life was increased but the production was considerably reduced. The grinding room was being pushed hard by the other departments and finally asked our help to speed up production.

The first step was to analyze the cost of grinding. This cost was divided into three items: wheel cost, labor cost, and overhead. The latter was found to be the largest item or approximately 90c per man per hour. This being the case it could easily be seen that a hard wheel would increase the overhead per unit ground while a soft one by cutting faster would decrease it. There would be a certain point of course where softer wheels would increase the wheel cost per unit sufficiently to offset the increase in production. After weeks of careful record keeping and experimenting with a wide range of grains and grades, it was found that by using grain 20 grade R the cost per unit of production was greatly decreased and the production per unit of time nearly doubled.

The figures are as follows:



Grain and grade	20W	20R
Average wheel life—hrs...	61.2	22.6
Steel ground off per hr. lbs.	2.4	4.1
Total cost per lb. of steel ground off	$ .57	$ .43

Figures for another example of exactly the same kind are as follows:

Grain and grade	20V	20R
Average wheel life—hrs...	60	39
Steel ground off per hr. lbs.	1.32	2.21
Total cost per lb. of steel ground off	$ .85	$ .61

Grinding billets and bars.

Attachment for machining large work on small lathe.

Hundreds of instances could be cited to show that a fast cutting wheel, one that will get the most out of all items of expense incurred in grinding, is well worth the experimenting necessary to determine it.

This company had been saving money on wheels to be sure, but after the tests it was quite apparent that this saving had been eaten up many times by slow production.

BENDING SHAPES

By J. Henry

A secret of easy bending is heating a small area to a bright red or yellow heat and bending no more than necessary. Several heats may be necessary, each followed by angular displacement which in the total restores the part to the original lines. Heating in a forge fire is at disadvantage for bending and straightening oftentimes because of the impossibility of confining the heat to a small section. Hence the bend cannot be exactly localized where wanted.

When bending structural steel it will be necessary often to cut flanges and remove parts to make the bends without distortion. The cutting torch is a most convenient tool for the purpose, of course. The cuts can be so made that the flanges are readily welded again after bending, thus producing fabricated parts of any shape, still having the strength and characteristic of the original section before bending.

INCREASING LATHE RANGE

In the small jobbing shop it is often desirable to increase the swing of a lathe to accommodate certain work, and blocking up the head stock and tail stock is generally resorted to. The sketch here shown is of a device designed to overcome the necessity of raising the head stock when a large piece of work is to be machined. The auxiliary head A is made to fit the shears of the lathe and of a height x to suit the possible range of work the plant will be interested in. The spindle B of the attachment is given a long support by extending the rear bearing over the front housing of the head stock. The pinion J is fitted to the threaded nose of lathe spindle and the boss on the back is made hexagon for easy removal with wrench. The pinions H and F are integral or keyed to intermediate shaft G, the pinion F driving the gear C, which is keyed to auxiliary spindle B, the forward end being threaded to take the ordinary lathe chuck or face plate. The dotted circles in Fig. 2 show the increased range of machine.

CARE IN PLACING LOADS

By R. J. Hamil

In the operation of machine tools, particularly lathes with long beds, a condition that does not always receive proper consideration, and one that may result in affecting the accuracy of the work being machined, is the indiscriminate placing of loads upon the floor in close proximity to the machine. Especially is this true where the lathe is located on wooden floors that are easily subjected to deflection or vibration. The placing of a heavy casting or load of any kind near the machine may cause the bed to sag or develop a wind, that will be transferred to the work being machined, and likewise affect the free running of the moving parts.

Care should be taken, when locating a long machine, to see that the supports are placed in such a way and in such a position that maximum rigidity will be maintained under all possible conditions. If it is necessary to locate the legs on a weak portion of the floor, care should be taken when placing other material of a heavy character close to the machine. It is best, however, to provide adequate support when the initial installation is made.

This applies likewise to line shafting located on the ceiling of the lower floors of factories, where heavy loads in the upper department may throw the line shaft out of alignment.

STEEL BLUE ON BRASS

Dissolve 1½ drachms of antimony sulphide and two ounces of calcined soda in ¾ pint of water. Add 2¾ drachms of kermes, filter and mix this solution with another 2¾ drachms of tartar, 5½ drachms of sodium hyposulphite and ¾ pint, of water. Polished sheet brass, placed in the warm mixture, assumes a beautiful steel blue.

GEAR CONSTRUCTION

(Continued from page 28)

or toggle punch presses, usually the latter. Drop forgings are sometimes called stampings, but that is stretching the term. The stamping process is specially applicable to blanks for sprockets and similar thin work.

Rolled bar steel is the common material for pinions. It is usually sawed to length in either rotary cold saws or power hack saws, and finished in lathes. As it comes from the rolling mills its finish is rough and it is usually not very straight, but this is immaterial when it is to be sawn up into short pieces.

Cold drawn steel is the same material as the above, finished to accurate size, straightness and smooth surface, by drawing through a die. For pinions it is round, but for racks it is drawn square or rectangular. This is the best form in which to use bar steel in automatic, screw machines, etc., for the production of small pinions where the bar revolves, as only a truly straight bar can be safely revolved at high speed, and also uniformity of diameter is necessary to work properly through the automatic chucks and bar feed mechanisms of this class of machine.

The surface metal of cold drawn bars is compressed by the process and placed under tension. This manifests itself when teeth are cut in one side of a bar for a rack. The surface or skin tension on that side is relieved, and that on the opposite side pulls the bar into an arc of a circle, so that it must be straightened before using. If the skin is milled or planed off the back, this effect is minimized.

Heat Treatment

The heat treatment of steel-gears is far too big a subject to be considered in any detail here. In brief, steel can be used, in addition to its natural state as it comes from the rolling mill or forge, in three heat conditions, in each of which the selection of a steel of suitable analysis is presupposed, for any one steel could not be treated at will in any manner. First, a steel with a carbon content of over .45 per cent. may be hardened by heating above the critical point and quenching.

Second, any steel may be heated above the critical point but not quenched above that point. This will be called a toughening or an annealing process, according to the rate of cooling. Both of these processes aim to control the maximum temperature in order to refine the grain of the steel.

The third process goes farther, in that it actually changes the chemical constitutents of the steel. This is the cementation or case carbonizing process, by which a steel too low in carbon to be hardened, say .20 per cent. carbon maintained at a high temperature for several hours in an atmosphere of carbonaceous gas, from which the surface steel abstracts carbon. By suitable choice of the material which gives off the gas, and regulation of the temperature and time, the carbon content can be raised at the surface to over one per cent. and driven into the steel to a considerable depth, far beyond what is necessary in gear work.

This is followed by heat treatment, consisting of heating and quenching one or more times, at temperatures selected to give a strong tough core to the gear tooth, enclosed in a hard dense case which will resist wear. The scientific regulation of temperatures at all stages of the process is of extreme importance. For instance, under correct regulation of the carbonizing heat the high carbon case merges gradually into the low carbon core, with no sharp line of demarcation, thus preventing any tendency for the case, which is always more or less brittle, to shell off from the core.

In this, as in all heat treatment, microscopic examination of polished and etched specimens is one of the best indications as to the results being obtained in the furnace room. All furnaces should of course be equipped with reliable pyrometers, preferably of the recording type, where the importance of the work warrants the expense, and all thermo couples should be checked against standards at intervals.

(To be Continued)

PRACTICAL MINING

(Continued from page 26)

mines or in some of the mills or testing laboratories, or in some cases they engage in prospecting or assessment work. In this way an easy and natural transition is made from the school to the responsibilities of life.

Importance of Industry

The importance and possibilities of the mining industry in Ontario are too often not appreciated, especially in the southern part of the province. With almost a monopoly of the world's nickel supply; with great deposits of copper, silver, and iron; and with gold mines rapidly approaching the point where they will take first rank in the world as producers; not to mention the numerous minerals as yet of unrealized value such as cobalt, Ontario stands easily in the premier position of Canadian provinces, and is probably without equal in the world for variety of minerals and possibilities for the future. The responsibility of training a sufficient number of Ontario boys to become men of skill and character for the development of these unsurpassed natural resources rests heavily on the institutions engaged in this training. Needless to say those in charge feel this responsibility keenly. They also feel that the institutions at Haileybury, Sudbury, and Timmins, might profitably be attended by students from other parts of the province who feel attracted to the mining industries.

Sand blasting as applied to the cleaning of steel is an idea of recent origin and has become popular with engineers everywhere.

HOW INDUSTRIAL ACCIDENTS CAN BE PREVENTED

(Continued from page 22)

need not be great, and the work would need to be handled with care and judgment. Harm instead of good I think can easily be done by too much paternalism or ill-considered action. The best rehabilitation is to get the workman back if possible into the same or some other occupation in the employment in which he was injured.

In conclusion I wish to thank the employers of the province for the co-operation given in the administration of the act. We all desire an efficient, impartial and satisfactory administration, and employers generally have assisted, especially in attending to the exceedingly important matter of reporting accidents and giving necessary information promptly, without which speedy payment of claims is impossible. Our task is a heavy and responsible one, and never more difficult than at the present time. We are a buffer between the different parties. Workmen and doctors sometimes complain that we pay too little money; employers often think we pay too much. Demands from various sources are being constantly made with which we cannot honestly comply. In dealing with compensation and assessments the Board is a judicial body and must do its duty, in accordance with the provisions of the Act, as we are sworn to do it, without fear or favor. The influence and pressure that is too frequently attempted must be resisted no matter what the consequences.

We are not always able to do all that we would wish but, whatever the shortcomings, injured workmen and their dependents were never before looked after as they are being looked after now; and if our task is heavy it is an honor and a privilege to have so great an opportunity of doing good and of rendering useful public service. I believe upon the whole there is no better Workmen's Compensation Act in existence than our present one. It makes for better relations between employer and employee; provides relief for all accidents of consequence in employment; keeps the employer immune from actions in the law courts; and speedily, without litigation or expenses, puts directly into the hands of the bereaved widow or the crippled or injured workman $98 out of every $100 the employer has to pay for accident protection. Though the benefits are liberal the rates of assessment, by reason of the absence of overhead and other expenses incident to other systems, are not high in comparison with those in other places; and if you will reduce the accidents, the rates of assessment will automatically also drop.

Northern Cranes & Hoists is the title of a small booklet just issued by the Northern Crane Works of Walkerville, Ont. It contains a number of illustrations of their various types of cranes and hoists under different working conditions.

New Things in Shop Equipment

SPROCKET TOOTH HOBS

A new line of hobs for cutting teeth in sprocket wheels has recently made its appearance on the market. Each hob of the set is suitable for cutting any number of sprocket teeth of a given pitch and roll diameter. Thus it is claimed that each hob will do the work that ordinarily requires from six to nine cutters. In addition, when teeth are hobbed high production rates and accurate indexing is obtained. The hobs are designed to cut teeth in conformity with practically all the recognized standards. The tooth form possesses some interesting features which adapts it for production by hobbing. Its space angle gradually decreases as the number of teeth increases. The generating action of the hob tends to produce these changes, although not at the same rate. The pitch of each hob is greater than the circular pitch of the sprocket for all above a certain number of teeth, and less than the circular pitch for all under that number. The hobs are manufactured and marketed by the Diamond Chain and Mfg. Co., of Indianapolis.

IMPROVED LATHE CHUCKS

An improved line of lathe chucks made in all sizes from ten to thirty inches has recently been placed on the market. A special feature is the thrust bearings which are made in two parts and completely encircle the screws at a point about midway of their length. The stems of the thrust bearings are driven into round holes in the chuck body and are therefore self-aligning. The bearings hold the screws in place whether the jaws are assembled or not. The complete line of chucks are manufactured and finished to gauges and therefore spare parts are interchangeable. The Cushman Chuck Co. of Hartford, Conn., are the manufacturers.

AUTOMATIC CUTTING MACHINE

An automatic cutting machine intended for cutting such metal parts as dies, cams, crankshafts, and drop-forge tools, directly from steel plates, has recently been placed on the market. The machine has two carriages, one of which is mounted on the other. The upper carriage has on one side an oxy-acetylene cutting torch, and on the opposite side it supports the driving and tracing system. Any movement on the pattern is transmitted directly to the torch. A motor on the top carriage is used for power. This power is transmitted through a friction wheel. The machine is manufactured by the General Welding and Equipment Co. of Boston, Mass.

WORM-GEAR DRIVE FOR LINE SHAFTING

There has been placed on the market an enclosed worm gear unit for driving line shafting direct from a motor attached to the ceiling. The armature shaft is, of course, set at right angles to the line shaft. The apparatus has been designed to enable the smaller high speed motors to be utilized for line shaft drives, that are positively connected. At the same time large ratios of speed reduction can be provided. The manufacturers are the Cleveland Worm and Gear Co. of Cleveland, Ohio.

BUFFING AND GRINDING MACHINES

A recent devlopment is a line of floor-type buffing and grinding machines on which the motor is totally enclosed and its shaft is extended and threaded at both ends for accommodating the grinding and buffing wheels. The standard is of cast iron and carries the motor housing. A safety switch is placed on the front of the pedestal. A pulley is provided on the motor shaft for the driving of an air compressor if it is required to do so. The Valley Electric Co. of St. Louis, Mo., are the manufacturers.

PORTABLE BAND SAW

Recently there has been offered on the market a pattern-maker's band saw that is portable. The saw is driven by an enclosed electrical motor of ½ h. p Current can be supplied from any ordinary lighting circuit. The motor is positively connected to the lower saw wheel by a fabroil gear and a steel pinion, both of which run in oil. The motor speed is 1750 r. p. m. The machine is equipped with disc wheels. The table is a ground plate mounted on rocker bearings which permit of an adjustment from 45 deg. in one direction to 5 deg. in the other. An indicator shows the angle at which the table is tilted. All the adjustments are made without the use of a wrench, as handwheels and thumb screws are provided in all cases. The saw blades are made from a special steel and are operated at a speed of 3150 feet a minute. The table is 19 by 21 in. and is located 42 in. from the floor. The total overall height of the machine is about six feet. The manufacturers are J. D. Wallace & Co. of Chicago, Ill.

THERMALOAD MOTOR STARTER

This type of starter which has been recently designed for controlling the operation of alternating current, single-two-, and three-phase motors of from ¼ to 10 h. p., is well adapted to machine tool application, in that the number of control stations, which are of the push-button type, may be located in several convenient positions on a machine, so that the operator can instantly stop the machine when he desires. In the event of the load on the cutting tool becoming too great, the appliance immediately stops the motor. At the same time the apparatus allows the motor to exert six or seven times its normal power for momentary loads, or loads of very brief duration. In addition to this protection to the motor and machine, it also protects the motor from prolonged overloads as small as twenty-five per cent., and from overheating sufficiently to cause injury to the insulation. Polyphase motors are also protected from running on single-phase current. The starter is being manufactured and marketed by the Monitor Controller Co. of Baltimore, Md.

SAFETY DRILL AND TAP CHUCK

A safety chuck for use with drills and taps and having a positive drive, has recently been offered for sale. It has been designed principally for use where hand feed is employed. The present models of chucks are for small drills and taps, where the percentage of breakages is high. The safety device by means of which such breakages are prevented consists of two friction members and a soft steel driving pin, which pin is sheared when the tool is overloaded. The tool is held in a hardened collet by means of a Bristo hollow safety set screw, which bears on a flat on the tool shank. The soft steel driving pin is inserted through the collet and a hardened male friction member which is adjusted by the knurled nut on the outside of the chuck body. The female friction member is keyed to the body, the nut bearing on it, and thus preventing it from tightening or loosening, when the tool is run forward or backward. When the resistance to the tool becomes too great so that it sticks, the pin is sheared. There are three sizes of pin holes in the standard collet, the smaller ones being used with high speed drills. The pin is held in place by a spring plunger. The chuck is manufactured by the Save-All Tool Co., of Waltham, Mass.

SAW-CHIP REMOVING DEVICE

It has been definitely determined that the breakage of metal-cutting saws is very often caused by the clogging acti of the chips, which causes a heavy strain to be placed on the teeth. To eliminate such a condition a special wheel has

been brought out. It has teeth spaced to suit the teeth of the saw with which it is intended to be used. It is attached by means of a stud to some member adjacent to the saw, and is placed at right angles to one side of the saw in such a position that the teeth of the wheel engage the tops of the saw teeth as the saw revolves, and push the chips from these surfaces. As the saw teeth are kept free from chips when the device is used, the saw itself can be operated at faster speeds and with heavier feeds. The wheel is manufactured by Henry Disston & Sons, Inc., of Philadelphia, Pa.

STAGGER-FEED PUNCH PRESS

There has recently been placed on the market an automatic punch press on which the punch operates continuously and cuts blanks in a staggered relation to one another. When discs are being produced the machine leaves only a mere thread of metal between the holes punched out of a strip of stock. The machine is particularly suited to the production of such parts as can tops and bottoms and other small shells. The sheet stock is held in a carrier which travels in either direction past the reciprocating punch. It is not necessary for the carrier to be returned to the starting point after punching a row of blanks, because the moment the end of the row has been reached the action of the carrier is automatically reversed, and the next row may be punched as the carrier returns to the starting point. After the last blank has been punched from a sheet the carrier stops automatically. It is thus possible for an operator to run several machines at one time. His safety is provided for as at no time do his fingers come near the die. Another feature of the machine is that the scrap is automatically ejected. The machine will produce blanks from one to four inches in diameter and has a capacity up to 100 pieces a minute. The machine is manufactured by the Adriance Machine works, Inc., of Brooklyn, N. Y.

COMPOUND-SEAM CLOSER

A machine that is capable of producing air tight side seams on such articles as drums for calcium carbide and cans for calcium chloride has recently been placed on the market. The seam may be filled with a sealing compound, although the seam as closed by the machine is practically air tight. Offsets are first formed on the ends of the sheet to be joined, after which the sheet is rolled to a cylindrical shape and placed over the horn of the machine, with the offsets lying on the guide piece set into the top of the horn. The machine runs continuously and for that reason is not provided with tight and loose pulleys, or a clutch. The drive-pulley runs at 100 r. p. m. The treadle at the front of the machine is connected to a sliding member, and by depressing the treadle the work is moved forward along the horn and fed between the first set of rolls, which squeeze the seam together at the bottom. After these rolls take hold, the work is automatically fed through the machine. The second set of rolls flattens, and thus closes the double lock seam in one operation. The maximum length of work that can be handled in the machine is 42 in., and the minimum diameter for that length is 13½ in. The machine can handle material up to No. 22 gauge, soft steel. The weight is approximately 2700 pounds. The manufacturers are the Niagara Machine & Tool Works of Buffalo, N. Y.

SIMPLIFIED CUTTING TORCH

A new cutting torch has been designed, where two tubes instead of three, connect the head with the handle, and in which the pre-heating gases, either oxygen or acetylene or some other combustible gas, are mixed in the chamber between the handle and the head. The design requires a new style of tip. This is necessary as the gases are mixed before they reach the tip. The head is a copper forging which is free from pin holes and other defects, and can resist higher temperatures than bronze or brass castings. The ratio of the mixed gases is controlled by two needle valves. The cutting-oxygen valve is operated by a finger lever which can be placed and left in either an open or closed position. Thus the operator can cut work without holding his finger on the trigger after the operation has been started, and when he wishes to stop cutting, a reverse pressure on the trigger closes the valve. A spring holds the trigger in the closed position until it is operated again. The back end of the torch can be easily removed if it becomes necessary to clean the screen or to remove the oxygen cutting valve seat. The tips are made of copper and are held in a taper seat by a bushing nut. The tips are made with the cutting-oxygen hole at the centre and the preheating holes surround it. The number of pre-heating holes in a tip varies from two to six, depending on the combustible gas used, the manner in which the torch is applied and the metal being cut. For the purpose of cutting off rivets bent tips are supplied. Gases less combustible than acetylene and those that burn with a flame of lower temperature, such as butane, hydrogen, carbohydrogen, and illuminating gas, can be used. Best results are obtained, however, with acetylene as smoother and more even cutting is obtained. The torch is manufactured by the Davis Bournonville Co. of Jersey City, N. J.

In sand blasting steel, it is necessary to maintain a high and even pressure, as a low pressure will not cut off rust and scale entirely. When a high pressure is used, the rust and scale disappear and the steel is polished like dull silver

PORTABLE GAP LATHE

A very interesting, and at the same time a very useful, little machine tool has recently been placed on the market in the form of an 11-in. gap lathe having a maximum distance between centres of 24 in. The tool is so small that it may be used as portable equipment if it is so desired. There is furnished a quick change feed-box which consists of a clutch for engaging and disengaging the feed. A crank handle is provided for traversing the carriage when working on short jobs close to the face plate. Below the gap there is a shelf which serves as a support for the carriage when it is run over the gap. An adjustable plug, which is fitted on the left end of the apron, bears on the planed surface of the shelf and withstands the downward pressure. When working on jobs that require the carriage to be near the tail stock end of the lathe, the crank handle operating the carriage can be removed from the left hand end of the lead screw and placed on the right hand end, a short extension of the screw protuding from the end bearing for this purpose. The feed box offers a wide range of threads to be cut, which range includes all standard threads from 8 to 224 per inch, inclusive, and also the 11½ threads required for pipe threading. Reverse gears are also provided for the cutting of both right- and left-hand threads. The reverse gears are located within the swinging quadrant at the end of the head-stock. In addition the quadrant also contains compound gears for the drive within the feed box. A sliding tumbler lever engages any of the cone gears while a direct reading index-plate on top of the feed-box designates the proper position of this lever for any desired feed. The cross slide may be swiveled for angular turning, and when set for straight facing, taper dowel pins serve to locate it in its proper position. The counter shaft is mounted in self aligning bronze bearings secured to the rear legs. It may be driven direct from a line shaft through its friction pulley, or by a motor mounted on the bed. The friction pulley is of the cone type having a spring that keeps it in engagement. A vertical rod at the rear of the machine has a fork that engages the flange of the friction clutch. This rod is operated from the front of the machine by a lever. A braking action is exerted on the countershaft by this lever when the clutch is disengaged, and is sufficient to stop the countershaft instantly. The drive from the countershaft to the head-stock is through the medium of a three-step cone pulley. Back gears are provided which permit of six changes of spindle speed in geometrical progression. The motor recommended for this lathe is of ½ h. p., and can be supplied with current from an ordinary lamp socket. The swing of the machine at the gap is 16 in. and over the carriage 8¾ in. It is manufactured by the Artisan Mfg. Co. of Cincinnati, Ohio.

Figures Show Alarming Total

ON ANOTHER page of this issue appears an article dealing with Ontario's Accident Prevention Policy. It covers the work which has been done by the Workmen's Compensation Board, and while it is an able report, the fact remains that compensation only mitigates the result of accident, but does not restore the life destroyed, or the limb lost or crippled.

In 1921, 45,191 accidents were reported, 386 of which were fatal. During the seven years in which the Workmen's Compensation Act has been in force, there have been 272,000 accidents, 2,784 of a fatal character. This figure equals the combined population of Hamilton, Ottawa and Windsor. It is an alarming total, and yet it only includes the industries covered by the Act. Many other accidents are never reported, so that it simply makes an extremely bad situation all the worse.

A surprising and significant fact is, that less than one-third of all accidents occurred on machinery. The other two-thirds were caused through carelessness in one form or another. Stepping on, and knocking against objects caused 2,455 accidents during the year, while 10,609 resulted from the handling of material, loading, piling, etc. This clearly shows that accident prevention does not stop with the guarding of machinery, but that the state of mind and attitude of all workmen from the manager down is most important.

Another disclosure is that a large proportion of accidents happen to employees starting on a new job. This can be avoided by foremen taking more pains to explain the operation, and see that the new worker understands the task, before being left to his own devices.

A regrettable fact is that the report shows that several accidents could have been avoided through the use of goggles, and that molders were not making sufficient use of protective footwear. The increase in injury to young boys should be carefully investigated, and the cause removed at once, for the youth of our land must not grow up disabled and unfit.

The evil consequences of seemingly trivial cuts, is once more emphasized in the report, and we can only add to what we have often previously advocated, (i. e.) no matter how slight the cut or bruise, see a doctor at once, you owe it not only to yourself, but your dependents as well. Blood poisoning caused at least one-eighth of the total accident cost, or approximately three quarters of a million dollars. Surely this staggering total is sufficient answer for the careless and skeptical.

Manufacturers and employees should make it a point to lower the accident toll this year, and this can only be done through close co-operation. Workers should report any unsafe conditions to the foreman, and if he fails to immediately remedy the evil, report it still higher up. On the other hand let manufacturers co-operate with the men, and once a danger spot is reported, see to it that the trouble is remedied. The editorial following proves this point admirably for had proper inspection taken place, the report would have been made, the danger eliminated, and another home would still have the breadwinner at its head.

Something Wrong Here

AN EMPLOYEE of a brickyard in Toronto was killed the other day while attempting to put a belt on a shaft while in motion. The end of the shaft projected beyond the pulley, and the unfortunate man was dragged, caught through his clothing on the end of the shaft, and practically smashed to pieces.

Some interesting facts anent the system of factory inspection were brought out during the inquest. First of all, it was established that no copy of the factory act had been exhibited in the place for over five years. It was over a year since there had been a factory inspector in the place. One factory inspector giving evidence, said the place used to be in his district, and when under his jurisdiction he had ordered some guards to be placed around shaft or pulleys. He had been to the factory since the accident, but didn't notice whether his recommendations had been carried out or not.

The inspector now in charge of this district admitted that he had not made any visit to the place before the accident, giving as his reason that he did not know of the existence of the factory. He stated that when an inspector took over a district, he had to hunt out the factories in it, as there was no list provided.

There is a strong supposition from the evidence given at this inquest that had this accident not occurred, everything would have gone on in the same old way until something did happen. Preventive measures were not considered, and it does not seem to have been any one's business to look into the matter. There is a safety league convention in Toronto this week, preaching the gospel of safety first. There is a factory inspection department, and there are inspectors appointed and drawing a salary for preventing just such accidents as the one under discussion, yet according to the evidence of one of these inspectors the department has no information of the factories supposed to be under its jurisdiction. The inspectors have to "hunt these places out."

What seems to be needed is a factory inspection department that will inspect.

Sticking To The Task On Hand

THOMAS A. EDISON is noted for his wonderful personality and faculty for embracing the other man's viewpoint. He is spoken of as a man remarkably free from jealousy and eager to hail a new discovery. He firmly believes that a day's work means to complete as much as possible in the time.

Practically every successful man will give you the same recipe for success, viz., hard work, keep up interest in the job being performed, and study in your leisure moments. When we are inclined to feel dissatisfied with our present position, a self analysis is often a good medicine. Usually we discover that we ourselves are to blame for not having advanced further up the ladder of success.

Reductions and Increases Both Announced

Drills Come Down While Grinding Wheels and Pig Iron Go Up —Iron and Steel in Seasonal Demand—Small Tools and Supplies Taper Off Slightly—Scrap and Non-Ferrous Metals Weak

REDUCTIONS OCCUR IN SEVERAL LINES

CARBON and high speed drills are down in price. The decrease is approximately 10 per cent., and takes effect April 6. A machine tool manufacturer will also announce within a few days a reduction of 15 per cent. on his line of pipe machines. Another firm announce an increase in price on grinding wheels. These are the chief items of interest in the Canadian market.

Keen competition exists in the small tool field, but striking an average of business closed, March sales are at least 15 to 20 per cent. ahead of February, and in a few cases as high as 26 per cent. Compared with normal however, the average selling rate is about 50 per cent.

The demand for iron and steel shows seasonal improvement, and prices are firm in all lines. Orders are more numerous and much easier to secure than formerly. Much business shows considerable increase over February, and from present indications, April will be still better.

Machine tools are merely holding their own, but more new tools are being asked for than formerly. Prices are uncertain, because where the order is particularly desirable, keen competition and price cutting exists. Second hand and re-manufactured tools continue to move in reasonable quantities.

The same conditions hold true in the small tool supply business, prices in many cases being cut to a very low level. The recent influx of orders from the automotive industry has died down during the past week, and April business so far shows a slackening off.

Scrap metals remain inactive, non-ferrous metals being especially weak. New metals in the latter mentioned class are also in poor demand.

Pig iron shows an improvement, and prices are somewhat firmer. Small foundries are beginning to pick up, and as their stocks of pig are low, it means more business for the mills.

Oils, greases, and waste are selling at about the same rate as last week. Prices remain unchanged. Building is picking up quite a bit, and in the Montreal field added interest is being shown in structural material. So far, the railroads have not entered the market.

Reports from the American Iron and Steel Institute, show that steel ingot production in March increased more rapidly than anticipated. The rate on April 1, was approximately 35,000,000 tons a year, or practically equal to the total capacity in existence in 1914. If compared with present capacity, it equals about 66 per cent., as there has been an increase of about 50 per cent. in capacity since the war started.

The existing high rate of increase is not expected to continue for if such were possible, another five months would see production up to entire capacity. Unusually low stocks, extreme lowness of prices, and fear that the coal strike would interfere with production and shipment are really the causes for the rapid improvement. It is likely that the rate of increase will soon strike a level, tapering off in the summer when the steel market is always dull.

Prices in steel continue to show strength, and a few advances have taken place. Plates are now 1.50c, and most of the wire mills in the States have increased their prices on nails, staples, and barbed wire. Sheets are up $3 a ton, and mills have withdrawn all old prices.

Basic and foundry grades of pig iron are up 50 cents, Pittsburgh prices being $21.50 for Bessemer, $18.50 for basic, and $19.50 for foundry, f. o. b. valley furnaces, with $1.96 freight to Pittsburgh. The Buffalo market advanced $1.00 practically overnight, and it is thought that further advances may be announced later.

Toronto

April 12, 1922

THE IRON and steel trade continues to show seasonal improvement, but nothing more. The business being closed was expected, and in some cases, dealers claim they looked for a greater volume of orders. However, the average merchant feels he is getting his share. Prices remain firmer, but no increases are as yet reported, following up the recent advance in the States. Competition is too keen to allow for the advance, but another week may see a slight increase, as dealers are selling on a very close margin. Although merchants deny any knowledge of price cutting, there are isolated cases where desirable orders have been taken at reduced prices. Usually this is skillfully covered up, but nevertheless it exists. It is impossible to speak of any line moving better than another as the demand is general. Following are existing quotations:

Iron bars	2 75
Steel bars	2 75
Reinforcing bars	2 75
Steel hoops	3 75
Tire steel	3 00
Spring steel	6 00
Band steel, No. 10 gauge and 3-16 in. base	3 25
Small shapes	3 00

Pig Iron.—The demand for pig iron shows considerable improvement. Small foundries all over the country are showing signs of activity, and as their stocks of pig are exceptionally low, it means that the majority of this business is for immediate delivery. When the coal strike became operative April 1, one large producer of pig iron was fairly swamped with orders for a few days. Evidently users dreaded the possibility of a railroad tie-up as well as a coal strike, and ordered almost recklessly. This panicky feeling has passed, and orders being received are more conservative in character.

The price locally remains the same, $27.15, and if anything an increase, rather than a decrease can be looked for, as prices on the other side have advanced during the week.

Non-Ferrous Metals.—The demand for non-ferrous material remains poor. Prices are stationary, and as long as the consumer stays uninterested, it is doubtful if any change upward or downward will take place. The following table shows present quotations:

Lake Copper	17 00
Electric Copper	17 00
Castings, copper	16 50
Tin	34 00
Spelter	7 25
Lead	6 75
Antimony	8 00
Aluminum	26 00

Scrap Metals.—There is absolutely nothing of importance moving in this section of the market. Nobody wants to buy, and few wish to sell to the dealers, prices offered being so low. In other cases, dealers do not care to stock up further even at low prices, so things remain at a standstill. Present quotations are as follows:

Copper, light, per 100 lbs.	8 00
Copper, crucible	10 50
Copper, heavy	10 50
Copper wire	10 50
No. 1 composition	8 50
New brass cuttings	6 00
Red brass turnings	6 00
Yellow brass turnings	4 75
Light brass	3 50
Medium brass	4 50
Scrap zinc	3 25
Heavy lead	4 00
Tea lead	3 00
Aluminum	10 00
Boiler plate, per gross ton	9 00
Heavy melting steel	10 00
Axles (wrought iron)	16 00
Rails (scrap)	10 00
Malleable	11 00
No. 1 machine cast iron	16 00
Pipe, wrought	6 00
Car wheel	16 00
Steel axes	15 00
Mach. shop turnings	6 00
Stove plate	14 00
Cast boring	5 00

Machine Tools.—This section of the market merely holds its own. Several orders have been closed over the week, but nothing of importance. They are only for small machines, and the total value does not amount to much. An encouraging note, however, is that more

new tools are being asked for than formerly. Second-hand and re-built machines are moving at a fair rate, and while March business was not all that dealers could have wished for, it showed signs of promise. One manufacturer will announce in a few days a 15 per cent. reduction. Enquiries are numerous, and more serious in tone, many dealers feeling that several good things are about to break.

Small Tools and Supplies.—Although this market showed a decided improvement in March over February, the orders received so far this month are discouraging. It is interesting to note, that the average rate of increase in March business over the former month varied from 15 to 20 per cent., with a few exceptions being as high as 26 per cent. Some merchants feel that the remaining days in April will show up to better advantage, but time alone will tell whether their confidence is justified. Drills have dropped about 10 per cent., and keen competition exists.

One firm feels that general business in light machines and small tools shows sufficient signs of promise to justify the placing of two more travelers on the road, and have done so during the week. To show that increases as well as decreases can occur, a Canadian concern announces an increase in the cost of grinding wheels. They claim that the various reductions made from time to time have not been followed up by corresponding labor reductions, so that they now find the margin too fine. Manufacturing costs are so high, they claim, that the increase is absolutely necessary.

Miscellaneous.—The demand for oils and greases, waste, steel pipe, and other general lines remain about the same as last week. Steel pipe shows a very slight improvement, but hardly worth commenting upon. Prices remain firm, and are quoted as follows:

OILS AND COMPOUNDS

Castor oil, per lb.	34½
Royalite, per gal., bulk	21
Palacine	24
Machine oil, per gal.	33 00
Black oil, per gal.	17 50

Montreal

April 12, 1922

THE MORE or less spotty conditions that have prevailed on this market for the last few weeks continue. Reports are conflicting if taken at their face value, but a number of merchants, visited, say that their March business is better than February. The rate of increase varies, but taking everything into consideration, the trend is upward.

Iron and Steel.—Structural steel is in slightly better demand than for some months past and several large concerns, like the Dominion Bridge Co. and The Canada Car and Foundry Co., have been making a number of enquiries for steel. In fact several orders have been placed. It is believed that the material ordered is for stock. It is known that these firms are figuring on several fairly large jobs, and that the closing of any one would bring them into the market. A satisfactory volume of business has been placed in small lots by contractors, and this helps to swell the total.

Merchant bars are moving a little more freely, and sheets have shown activity during the week. So far, no further news of the railroads coming into the market has been received. Prices have not advanced locally, but viewed in the comparative light of the increases in the United States, it is not unlikely that prices here are due for a slight increase. Local quotations are:

Iron bars	2 75
Steel bars	2 75
Reinforcing bars	2 75
Steel hoops	3 75
Tire steel	3 00
Spring steel	6 00
Band steel, No. 10 gauge and 3-16 in. base	3 25
Small shapes	3 00

Pig Iron.—Although there has been little change in the pig iron situation in the city, the demand from smaller foundries in the surrounding country has been considerably better, and quite a tonnage has been booked. The price remains the same at $29.80 for No. 1 iron. Buffalo producers have booked a large tonnage of iron ore for water shipment, east through the Barge Canal, and west for delivery at lake ports as far as Chicago. The water rates are much lower than rail rates, and many places in New England can get a water rate for $1.50 per ton less than the rail. This additional business is likely to keep Buffalo furnaces busy for some time, and it is quite likely that the small advances in quotations will be followed by further advances. There is every reason to believe that local demand will increase when consumers feel that prices are on the upgrade because of a legitimate demand.

Machine Tools, and Supplies.—Machine tools have not shown any sign of moving yet. The demand for woodworking tools, which has been fair for some time past, is increasing, and a fair amount of business has been done. The recent reduction of ten per cent. on some lines has not been in effect long enough to ascertain to what extent sales have been stimulated. There still appears to be quite a movement in second-hand and re-manufactured tools. These are changing hands at very close figures, and prices have to be shaded considerably before a sale is made.

The small tool and supply business continues to be good. There have been no outstanding features for some time, but prices remain quite firm and the volume of business is gradually increasing. Dealers carrying miscellaneous supplies, such as pumps, valves, and a general line of power transmission are securing good business from sources outside the city. Many rural enterprises such as creameries and cheese factories, that carry on operations in the summer months only, are coming into the market for the season's supplies. In other lines there is the usual seasonal improvement, and on the whole conditions are encouraging.

Non-Ferrous Metals.—Although the non-ferrous metal market in New York and London has indicated a stiffening in practically all metals, there has not been any general upward revision of prices locally. There has been no increased demand, hence no changes have been made. For some time past the small volume of business present in local circles has only been holding its own. Present quotations are as follows:

Lake Copper	16 75
Electric Copper	16 50
Castings, Copper	16 25
Tin	34 50
Spelter	7 25
Lead	6 50
Antimony	6 50
Aluminum	23 00

Scrap Metals.—The demand for scrap metals fell off a little during the week. Manufacturing plants are not picking up very rapidly, and it is difficult to foretell just when conditions will change for the better. Until the larger plants resume operations on a greater scale, little or no improvement can be looked for. Prevailing prices are:

Copper, light per 100 lbs.	8 00
Copper, crucible	10 50
Copper, heavy	10 50
Copper wire	10 50
No. 1 composition	8 50
New brass cuttings	6 00
Red brass turnings	6 00
Yellow brass turnings	4 75
Light brass	3 50
Medium brass	4 50
Scrap zinc	3 25
Heavy lead	4 00
Tea lead	3 00
Aluminum	10 00
Boiler plate, per gross ton	7 00
Heavy melting steel	9 00
Axles (wrought iron)	17 00
Rails (scrap)	10 00
Malleable	10 00
No. 1 machine cast iron	18 00
Pipe, wrought	7 00
Car wheel	18 00
Steel axes	16 00
Mach. shop turnings	4 00
Stove plate	16 00
Cast boring	3 00

Activity along the waterfront has reached its height, and a new season of navigation will soon be opened. This should stimulate the general volume of business.

Pittsburg

April 10, 1922

SPECIAL TO Canadian Machinery.—For the third month this year the monthly report of the American Iron and Steel Institute, giving the March steel ingot output of 30 leading steel producers, has shown a larger output than trade reports during the month would have indicated. The increase has been so rapid that people have been unable to realize the unexpected climb.

In December the rate of production had fallen to a trifle below 20,000,000 tons a year. Rates in the first three months of this year have been as follows: January, 22,750,000 tons; February, 26,850,000 tons; March, 32,550,000 tons. These are equivalent to average rates during the respective months, and as production has been increasing, the rate at the beginning of a month would be under the average and the rate at the close of the month correspondingly above the average. Plotting the figures, it appears that the rate on April 1 was approximately 35,000,000 tons a year. As closely as can be estimated, this 35,000,000 ton rate is equal to the total capacity in existence in 1914, while it is equal to about two-thirds of the present capacity, estimated commonly at 52,500,000 tons, as there has been an increase of about 50 per cent. in capacity since the war started.

Encouraging Increase.—The rapid increase in production is very encouraging to the entire trade, sellers and buyers alike, but at the same time it sounds a note of warning. At the middle of last July the rate was barely over 10,000,000 tons, July as a whole having shown a rate of 11,000,000 tons. It is obvious that actual consumption has not tripled in less than nine months. General business has undoubtedly improved rather steadily, but there could be no such change as indicated by the figures. The extremely low production of last July was explained by buyers of steel being in the act of reducing their stock, and it is just as reasonable to assume that of late they have been replenishing their stocks.

The pace of increase cannot be maintained, for a continuance would in three months, i. e., by the middle of June, bring a rate equal to the record high rate ever seen, and in two months more the entire capacity would be in operation. Underlying conditions are not thus far justifying any such exhibition.

Viewing the matter in another light, experienced observers are practically a unit in asserting that actual consumption is at nothing like a rate commensurate with the production. The conclusion is that buyers have been adding to their stocks. No one criticizes them for that. The buyers have been moved by three considerations: (1) The fact that their stocks were at an unreasonably low level, too low for the efficient conduct of business; (2) The extreme lowness of steel prices; (3) Fear that the coal strike, begun April 1, would interfere with production or shipment of steel.

The very rapid increase in steel production in the past three months therefore is not an argument that production will continue to increase in like manner but rather an indication that soon it will stop increasing, while in summer, when the market is always dull, there will probably be a declining rate in production.

Prices Stiffening.—Steel prices continue to show a stiffening tendency all around. The recent advance in bars and shapes from 1.40c. to 1.50c. has been followed by a similar rise in plates. Probably in some cases 1.50c. is shaded in these three products while on the other hand small orders with mixed specifications generally command a little more than 1.50c.

Most of the wire nails have advanced their prices on nails, staples and barb wire $2 a ton, leaving plain wire and wire fence unchanged. Undoubtedly the advance will be complete in a day or two more, whereupon the market will be as follows: Plain wire, 2.55c.; galvanized wire, 2.75c.; wire nails, 2.50c.; polished staples, 2.55c.; galvanized staples, 3.15c.; painted barb wire, 2.65c.; galvanized barb wire, 3.15c.; wire fence, 68 per cent. off list.

Having entered, at the old prices, all the desirable business offered in sheets, the sheet mills have withdrawn old prices and substituted prices at the $3 a ton advance that it was announced recently would be made. A very heavy tonnage of shipping contracts was entered as buyers generally felt assured they would not lose by covering up to July 1. The new prices are: Blue annealed sheets, 2.40c.; black sheets, 3.15c.; galvanized sheets, 4.15c.; automobile sheets, 4.50c.

The coal strike inaugurated April 1, was practically 100 per cent. effective at the union coal mines. Some trouble was expected at non-union mines, but the strikes prove much more important than was expected. There are not a few strikes in Westmoreland County, including the Irwin gas coal field, and there are some in the Greensburg district and the basin of the Connellsville region. In the lower Connellsville or Klondike region the strikes involve much more than one-half the productive capacity. Practically all the mines along the Monongahala River are out.

This means that mills and furnaces will draw upon their stocks more this month than they had expected to do, for it was thought that the non union production of coal would be very nearly equal to actual consumption. Stocking has been general but not universal. The average merchant furnace, depending on Connellsville coke, did not stock to any extent, and some of these furnaces will in all probability be forced to bank. Some operators are talking high prices for coke, but the furnaces are a unit in asserting that they will not pay over about $3.50, as they cannot afford to do so, while the banking of a few furnaces will help the pig iron market which, they say, has been below cost of production. As a matter of fact basic and foundry grades are up 50 cents already, on the basis of sales made in the past two or three days, the market being quotable at $21.50 for Bessemer, $18.50 for basic and $19.50 for foundry, f. o. b. valley furnaces, with $1.96 freight to Pittsburg. Predictions are that basic and foundry will not stop at these new levels, but will advance another 50 cents, or more, within a very few days. The Buffalo market advanced $1 practically overnight.

ARE PLANNING A HOME PRODUCT EXHIBIT

SPEAKING on trade developments in Edmonton, Alberta, since the start of the year, John Blue, secretary of the board of trade of that city, tells Canadian Machinery that Edmonton business men have come through the winter in very good shape. There have been few failures. Trade has not been so good as was expected; but not because of financial conditions. Coal men have suffered a little because of the extremely mild weather that prevailed during the year.

"We have just closed the Home Building Exposition," says Mr. Blue. "This was a venture on the part of the manufacturers and distributors of building materials, and was regarded as a complete success being visited in the six days by nearly forty thousand people. It has created a considerable interest among the people of the city in building new homes. Building returns so far exceed last year's for the same period."

A number of new manufacturing firms, in a small way, have commenced business, namely: The Roberta Chemical Co.: The Renton Oil Production Co., The Bell Metal Products Co., and the Patricia Pharmacal Co., have extended their operations. The Edmonton board of trade is organizing an Edmonton home products exhibition. It was intended to hold this during horse show week at Easter time, but owing to lack of facilities the matter has been postponed until the summer fair. Arrangements are being completed with the exhibition association to give over a wing of the manufacturers' building exclusively to Edmonton manufactured goods.

"Unemployment has turned the minds of a great many men to manufacturing in a small way," concludes Mr. Blue, "Edmonton has many men who have been industrially trained in the old country and who, through force of circumstances, are turning their hands and their brains to doing something to earn a livelihood, and it seems to me that out of their necessity is bound to grow a considerable industrial development."

SELECTED MARKET QUOTATIONS

Being a record of prices current on raw and finished material entering into the manufacture of mechanical and general engineering products.

PIG IRON

Toronto price:—

News From the Industrial Field

The Kelsey Wheel Co., Windsor, Ont., is in the market for a 175 to 250 h. p. 3 phase motor.

Corr and Garrick, 148 Victoria St., Sarnia, Ont., are in the market for an air compressor.

The Wettlaufer Foundry Co., Mitchell, Ont., is in the market for modern equipment for a proposed foundry.

The B. and L. Laboratories, Aylmer, Ont., is preparing to erect a manufacturing plant in that city.

The Winchester Dye Co., of Trenton Ont., intends investigating Renfrew, Ont., with a view to establishing a branch there.

The E. T. Wright Co., Kelley and Wellington St., Hamilton, Ont., is in the market for drawing press 3½ x 3¾ second-hand preferred.

The Chamber of Commerce announces the establishment of a new factory in London, Ont., for the manufacture of electric furnaces.

A new wing will be built to the Ottawa University at a cost approximating $175,000. The contract has been secured by John Quinlan and Co. of Montreal.

The Frontenac Foundry Co., 388 Cartier St., Montreal, Que., is in the market for equipment for a new foundry on Latailleur St.

The Provincial Paper Mill, Port Arthur, Ont., is in the market for 73 book machines capable of turning out 15 tons of book paper per day.

The McQuay Tanning Co., of Owen Sound, contemplate a large addition to their tannery this season. Several other concerns in the district expect to enlarge their present facilities.

A new high school is to be built at Carleton Place, Ont. Additions will also be made to the existing school. A by-law to raise the necessary money will be submitted to the ratepayers at the earliest possible moment.

The Canada Electric Co., 175 King St. E., Toronto, Ont., have been awarded the contract for electric wiring on a consolidated school being erected at Wellington, Ont., at an estimated cost of $115,000.

Records indicate that a heavy trade has been carried on in lumber by vessels of the Canadian Government Merchant Marine. Reports for the past season show that 188,000,000 feet of lumber was exported from British Columbia to various foreign countries. This is a phenomenal increase over any previous year, the average for several seasons past not exceeding 40,000,000 ft. This business has come from practically all parts of the world.

Mr. C. Little of Robinson, Little Co., 343 Richmond St., London, Ont., plans to build an arena. The cost will be about $150,000. Prices wanted on artificial ice-making equipment.

The following figures show the receipts at the Port of Toronto, Ont., for the last three fiscal years. For the year 1919-20, $43,622,135. For the year 1920-21, $31,490,719. For the year 1921-22, $43,616,887.

The Universal Casket Co., has decided to locate its plant in Welland, Ont. A site has been purchased in Maple Leaf park just outside the city limits. The approximate cost of the factory will be $40,000. It is proposed to employ approximately 200 men.

Erection of four buildings at a cost of $1,500,000 is contained in a request made by the Toronto University to the Provincial Government. This program includes a new forestry and botany building, an administration building, additions to the heating plant and a woman's building.

Dominion Linens, of Guelph, report a big improvement for the past year. It was stated at the recent annual meeting that for the first three months of this year the business showed large increase over a similar period of 1921, and the management anticipate the enlargement of the company's three plants.

The Board of Education of St. Catharines, Ont., B. C. McBride, Secty., 13 Welland Ave., will receive bids until April 11 for a three storey, 175 x 313 ft. school, including a steam heating system with temperature regulators and mechanical equipment, on Geneva St. Cost will be about $600,000.

R. H. Cunningham and Co., industrial furnace engineers, of Walkerville, Ont., have secured temporary premises at 351 Glebe St. As there is a large demand for the type of furnace manufactured by Cunningham and Co. their output for some time is already disposed of and will provide work for a good many men.

The Board of Education at a meeting held recently at Peterboro, Ont. took another step towards building an addition to the collegiate institute, to not only provide greater high school accommodation, but also provide room for technical instruction, by appointing a committee to engage an architect to bring in the plans.

The volume of contemplated new work reported in Canada during March amounts to $23,753,100. Business buildings amounted to $5,267,200. or 39 per cent. of the total; industrial building $260,000,000, or 1.9 per cent. A significant feature of the March construction record is the increase in business building over February.

Arrangements are well advanced for the establishment of the London Bridge Company in London, Ont. Premises are being rented temporarily and no time will be lost in getting ready for the work of fabricating steel. This plant will form a valuable addition to London metal working industries and may be an important factor in securing of other metal working plants at this centre.

The Niagara River Bridge Co., owner of the cantilever bridge which crosses the Niagara River, announces that a new bridge will be built this year. An application to parliament will be made at the present session to increase the capital for that purpose. The old bridge which will be used until the new one decided on is completed. The bridge is used exclusively by the raiload.

L. H. Laythe, sales manager of the Butterfield Co., Rock Island, Que. stated to Canadian Machinery that the month of March 1922 was the best in the history of their business. This is all the more surprising due to the fact that they had a very bad time in the last year and a half. They are manufacturers of twist drills and similar tools.

A woodworking company of moderate size located in Toronto has made negotiations with the industrial committee of the city council of Galt, Ont. relative to the plant being moved there. The company in question is stated to be located in cramped quarters in Toronto and is looking elsewhere with a view to expansion. The company's proposition was placed before the board of trade and the city council of Galt two or three days ago.

The Renfrew Creamery is having its present refrigeration capacity doubled owing to the increase in cream business. The Linde Canadian Refrigeration Co., of Montreal, the same firm that installed the system is making the addition. During the year 1921, the creamery put out nearly a quarter of a million pounds of butter and 13,000 gallons of ice cream. The staff has also been considerably increased.

At present there is a movement on foot among business and industrial men in Italy for promoting better trade relations between Canada and that country. It has been suggested that an Italo-Canadian consortium be created to develop the relations between the two countries and it has been advised that yearly exhibits of Italian products be held in Toronto. The consortium which was appointed includes Signori Luigi Rossi, of the Italian Trade Department; William Clarke, Sir Charles Gordon, of Montreal, who is representing Canada at the Genoa Conference; Signori Padgetti, representing the Canadian Pacific Railway, and Cavalier Riccardi, Italian Consul at Montreal

Mr. Neilson, a representative of the Renfrew Refrigerating Co., Limited, Renfrew, Ont., has reported that their factory has been working at full capacity for some time and that the entire output is sold. We understand that they will not be able to take orders for quite some time until a good advancement is made in their output which is being increased every day. This firm manufacture Barnet Refrigerators.

A statement of the cost of the new filtration plant purchased by the Utilities Commission of Peterboro, Ont., showed that $25,000 has been saved in its construction, an unusual occurrence in municipal works in that city. Of the $350,000 appropriated by these people, only $325,000 has been spent. In laying the pipe lines themselves the commission saved over $10,000. The plant is now in full operation and the condition of the water is much improved.

An encouraging note was sounded the other day with the announcement that a Brantford roofing company has taken on its entire staff, full time, after being on a half time schedule. Regular business from all parts of Canada was stated by the president as the reason for the increase. He took it that the orders coming in were evidence of a revival of building and of reconstruction and replacement work throughout the Dominion as a whole, for no one section was carrying the load.

The English Electric Co., of Canada, which was organized in August of last year, and has taken over the St. Catharines plant of the Canadian Crocker-Wheeler Co., has just completed an order for traction equipment. Tests have been applied and it is understood that the work has been in every way satisfactory. The new equipment is founded on the designs and models owned by the parent company, the English Electric Co., that has been entirely made in Canada of Canadian materials.

As soon as the weather allows, work on a large scale will be commenced on section one and two of the Welland canal, which contracts are in the hands of Porter Bros. At present the Canal zone is very muddy, and work is being carried on with difficulty. Section three at Thorold, Ont., is under Government contract, but it is believed that this section and those about Thorold will soon be let to private contractors. A large amount of rock excavation is done on the Thorold section, which is the most expensive section on the whole water works.

Building activity in Ottawa promises to be considerably increased this summer if the permits taken out during the past month are any criterion. Some 80 permits were taken out as compared with the 45 issued in the corresponding month last year. Of these 24 are for buildings having an estimated valuation of $3,000 or more each. Largest is for an apartment house to be erected on Chapel street by Mrs. E. Roquet at a cost of $15,000. Mr. A. Lowe is to erect stores on Bank street costing $12,000 and the Salvation Army will spend $4,000 on an extension to its social center.

The Dexter Lock Co., of Canada, is the new organization that has been formed to manufacture patent door locks in Hamilton similar to those produced by the National Brass Co., of Grand Rapids, Mich. The location of the industry was announced last week by C. W. Kirkpatrick, Hamilton, Commissioner of Industries. The new company have secured premises formerly occupied by the National Machinery and Supply Co. The Hamilton company have secured the Canadian and British Empire rights for the line of products in question. O. W. Cook the president and manager of the new company, was formerly connected with the Canadian Cartridge Co. Production will commence as soon as equipment can be installed. Fifty workers will be employed at the outset.

Contractors and builders in Pembroke, Ont., state that during this coming season close on to a million dollars will be spent in that city. Part will go to erecting stores and places of business in the gaps left by the great fire of 1918, which destroyed much of the business section of the town. Owing to the high cost of building these were not replaced, but contracts have recently been given for business places to be built in these vacancies. This is only one of the many indications that Pembroke real estate men and builders expect the coming season to be an unusually busy one. Considering the population of this city is only 7,600 the above figure may be considered as being quite a substantial one.

The Marconi Co. of Canada, announce they will shortly install apparatus on the roof of the Canada Cement Building, Phillips Square, Montreal, for the "broadcasting," of messages, replacing the present installation at their plant. The change being made owing to the superior advantage of the greater elevation of the Canada Cement building. The company is also beginning the manufacture of individual wireless sets in response to the tremendous demand for same that is springing up with the prospects of a popular trade at the present moment. It is expected they will be turning out 10 sets a day within a few weeks.

Mr. Claire Mussen, president of Mussens Ltd., Montreal, Que., was given a tremendous ovation on his appearance at the Rotary Club meeting held in Montreal, this week, the first since the recent spectacular announcement of the press that Mussens Limited, after seven years of honorable effort had paid over 100 cents on the dollar to their creditors following the liquidation of the company early in the war. The announcement has aroused wide-spread interest in Montreal, and Mr. Mussen has been the recipient of congratulations on every side for such a satisfactory conclusion of the previous difficulties of the firm at a time when the tendency in general has been towards further liquidation, rather than the reverse as in the case of Mussens Limited.

The Electric Steel and Metals Ltd., plant at Welland has been sold. After weeks of negotiation a deal has been finally closed, and the plant bought outright by a large concern in the United States. The total amount of money involved in the purchase will be well over a half million dollars. This includes the purchase price and an allowance for certain new constructions planned for in the near future. It is understood that the new company is a wealthy one, and in a position to enlarge and improve the plant just as soon as the steel market warrants it. It is expected that for a time, part of the equipment now installed, will be used, but that eventually the whole place will be revolutionized. An addition will be erected for new machinery. It is anticipated that much of the output of the new mill will be exported. It was for this reason, largely, that the site of the Electric Steel was chosen. It is planned to build a large sized wharf on the new and large canal, where steel may be shipped direct from Canada by boat.

Compared to present day stagnation in industrial activity in many cities, Fort William's industrial section in the west end of the city shows considerable animation, and as the warm weather approaches activity will increase. Among the big plants in active operation there are the Canadian Car and Foundry Co., the Fort William Pulp and Paper Co., the Canadian Iron Corp., various grain elevators, and the Barnett and McQueen Co., who have under construction upon the north bank of the Kaministiquia River a two million bushel concrete addition to the north western elevator. Good progress is being made at the big plant of the Canadian Car and Foundry Co., where over 450 men are employed repairing railway cars for the Canadian Government Railways. The new plant of the Fort William Paper Co., at the mission is just about the most active location in the city. It is running to utmost capacity and three shifts of employees consisting of over 200 men are employed night and day. Lack of orders has forced the Canada Iron Corp. to cut their working staff down to 90 and to only operate 4 days a week. The big factory is employed now in the manufacture of car wheels, but in a short time a start will be made in the manufacture of iron pipe for stock purposes and the staff will be increased to 140 and the working days extended to the full week.

H. H. Camp of the Steel Co. of Canada, Hamilton, Ont., says that while business in the heavier lines is not picking up very much as yet, the lighter material is selling better. Pig iron demand has strengthened quite a bit, and foundries generally seem to be improving.

SIMONDS

Machine Shop Files

Highest Quality

Good files are as necessary in a machine shop as any other tool—In fact, files like Simonds are really essential for smooth work. All Simonds Files are made absolutely uniform and hold their cutting edge longer.

Mechanics should try Simonds Machine Shop Files.

Simonds Canada Saw Co., Limited

Montreal, Que.

St. John, N.B. Vancouver, B.C.

The steamer Britannic, well known on the St. Lawrence, is being overhauled and refitted by the Montreal and Cornwall Navigation Co.

Navigation opened at Kingston on Wednesday when the steamer Wolfe Islander cleared for Wolfe Island to commence her regular schedule.

The steamer Colin W. of the Webster Line, which has traded for many years along the St. Lawrence, is being converted into a fuel oil lighter to be used in Montreal Harbor.

A large staff of men are engaged in the work of repairing vessels that wintered at Cornwall. The twenty-six craft there will be ready for the season's operation within a few weeks.

The Dunn Motor Works of Ogdensburg are in receipt of an order from the Pacific Orient Co. of Bangkok, Siam, for a two-ton shipment of their motors.

The Essex County Health Association is asking for tenders on the construction of a $150,000 hospital on Prince Road, Sandwich, Ont. The building will house tuberculosis patients of the county. Cameron and Ralston of Windsor are the architects.

The Bell Telephone Co. has started the erection of an exchange in Walkerville, Ont., at Lincoln Road and Huron Street, to cost in the neighborhood of $100,000. Up to date the Windsor exchange has been handling the service for all the Border Cities.

The Prince Edward, the United Hotel Company's new 10 story, $2.500,000 hotel at Windsor, Ont.. will be ready to receive guests by June 1, 1922, according to a recent announcement by the management. Neville P. Mowatt of Flint, Mich., has been appointed local manager.

Jones & Glassco Reg'd. of Montreal and Toronto, have been appointed the sole Canadian agents for the Unchokeable Pump Ltd. of London, Eng. The Unchokeable Pump is constructed on the centrifugal principle, but so designed that fibrous solids, skins, sacking, etc., will pass through it without difficulty.

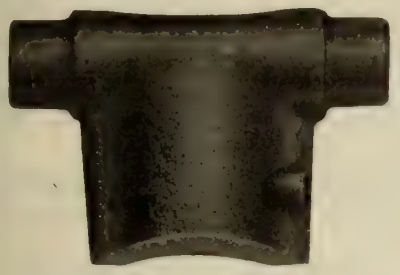
The navigation season on the St. Lawrence will probably open about the 24th of this month, according to an announcement by officials of the Canada Steamship Lines. The Toronto-Hamilton Montreal service will commence on April 20. The City of Hamilton and City of Ottawa have been assigned to this route.

Work on the four steel freighters for the George Hall Coal and Transportation Co., now being built on the yard of the Tidewater Shipbuilding Co. at Three Rivers, is proceeding satisfactorily. These boats are 260 ft. long, 44 ft. beam and 21 ft. moulded depth. Their canal capacity will be 2,500 tons in addition to bunker fuel. Five hundred men are employed on the construction of the vessels.

Building prospects in and around Ottawa are particularly bright. Permits for the year to date total about half a million dollars, an advance of approximately $82,000 over this time last year. The bulk of this is for private dwellings and stores but some industrial work is included. Business in Hull is also brighter, with the promise of a good season ahead.

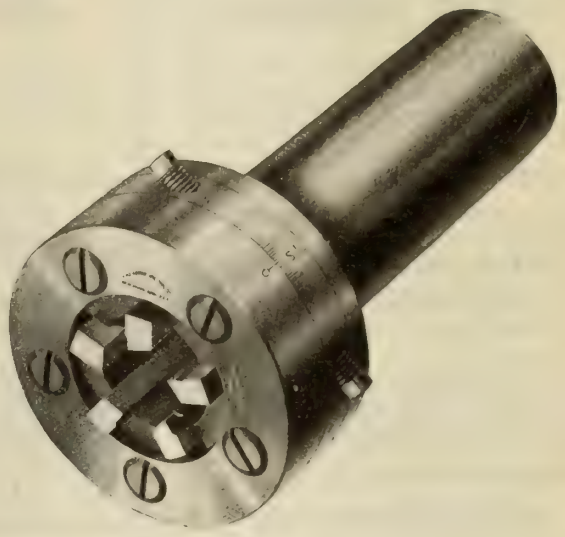
Mr. Skelton, vice-president of the National Steel Car Co. mentioned to Canadian Machinery a few days ago, that the truck business is picking up remarkably well. He says that orders are coming in more freely, and that the majority are for quick delivery. In fact a truck ordered for Vancouver was in such a hurry that test inspectors worked on it all night, even to test runs in order to speed up shipment. They expect to take on some further help in this department in the near future.

A. F. Healy of Windsor, Ont., has taken over the financing of the Detroit River Bridge. R. T. Scott has resigned the presidency of the R. T. Scott Company, Ltd., organized to sell the bonds of the Canadian Transit Co. and American Transit Co., and Mr. Healy is applying to the government to change the name to the A. F. Healy Company, Ltd. Mr. Healy is a director of both transit companies and of the Scott Company. Borings to locate the foundations of the bridge are still being taken but it is expected that the definite location of the bridge will be determined this month.



The Hamilton Foundry, Hamilton, Ont., are finding conditions somewhat improved. Orders from local factories are becoming more numerous, and while the quantity ordered is not very heavy, the total tonnage is increasing. Prices however are rather low, a very small margin of profit being allowed. In some cases, business is being taken at cost in order to keep the foundry going. So far no men have been let out, and it is very unlikely that this will occur now, for things seem to be improving slightly every week.

H. R. Williams, manager of the Beaver Truck Corporation, Hamilton, tells Canadian Machinery that business is picking up in a remarkable manner. He says that at the present time they have more enquiries on hand than they can comfortably handle, and that by next week they should be running in full swing. Almost double the volume of business over the boom period is marked on the books for quick shipment, and Mr. Williams says they look for a record year, as many manufacturers have put off buying as long as they could, but are now finding they absolutely require better truck facilities if they are going to keep in the swim.



2,000 Per Day

DROP FORGINGS TURNED DOWN 1/16"

With a Geometric Adjustable Hollow Milling Tool, 7,000 of the Pieces Reduced Between Grinds

Geometric Adjustable Hollow Mills are most effective and economical for reducing duplicate parts to an exact diameter prior to threading and for metal finishing. They are also used for milling brass, cast iron, steel forgings, castings and similar metals. Their use in place of the usual roughing and finishing box tools is quite desirable for general screw machine work where the milling is not too heavy.

Geometric Adjustable Hollow Milling Tools were designed to overcome the difficulties of their particular class of work. With the solid hollow mill, and the later spring finger hollow mill, when one of the teeth became broken, the entire tool had to be discarded and the expense of a new tool incurred. Simply renew the Cutters in a Geometric Hollow Mill, and the Tool becomes as good as new.

There is an extensive quantity of milling that is done with great economy by the use of GEOMETRIC ADJUSTABLE HOLLOW MILLING TOOLS.

Send for the Hollow Milling Tool Booklet. It tells what these tools are doing.

CLOSING TIME

Advertisements for this section must be in our composing room Tuesday morning prior to day of issue.

In order that the announcements of your wants, machinery for sale, etc., etc., shall not be delayed, please try to have them in our office with the Tuesday morning mail.

Canadian Machinery

SITUATIONS WANTED

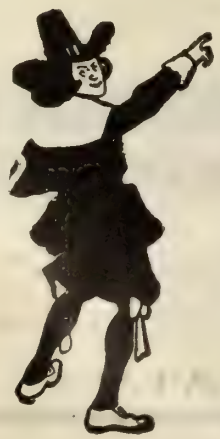
MECHANICAL ENGINEER IS OPEN TO consider partnership or interest with manufacturer with a view to producing new high grade lines of engineering equipment. Must have good reputation and manufacturing facilities. Box 808, Canadian Machinery. (C.16M.)

SALESMAN, 6 YEARS' MACHINE TOOL EXperience, 10 years general engineering with A1 practical and theoretical knowledge of mechanics, open to represent manufacturer in Toronto and district. Box 805L, Canadian Machinery.

SITUATION WANTED AS SUPERINTENDENT or general foreman of machine shop, twenty years' experience. At present employed; best of references. Box 861T. Canadian Machinery. (c23m)

PRACTICAL FOUNDRYMAN, 25 YEARS ON light, medium and heavy work, green and dry sand. Bench, floor and machine molding, melt by analysis, and thoroughly competent on cupola practice. Good reference. Box 804. Canadian Machinery. (C11M.)

FOR SALE



ONE J. & J. TAYLOR SAFE, INSIDE DIMENsions 15 inches deep, 2 feet 6 inches wide, three feet 11½ inches high and fitted with a built in compartment. Price $250.00.

ONE J. & J. TAYLOR SAFE, 18 INCHES deep, two feet 9 inches wide, four feet five inches high, fitted with a steel compartment. Both safes are in good condition and can be bought at a price that will save considerable money to the purchaser. Price $200.00. Box 806L Canadian Machinery.

FOR SALE:—ARCWELL ELECTRIC WELDing outfit, Heald Internal Grinder, 10 Pyrometers, Portable Crane, 5 Elevating Trucks, 1 four spindle drill, Sandblast outfit, several tool grinders, Warner Swazey screw machine 300 feet Matthews' Gravity Conveyor, 3 Tool Furnaces. This equipment almost new will sell cheap. Box 802L.

WANTED

CASH REGISTER WANTED—SINGLE DRAWer. Receipt printer. Must be in excellent condition. Box No. 807L Canadian Machinery.

Put it There!

No, we're not shaking hands, but we would like to offer advice.

These columns have sold hundreds of dollars worth of equipment. A large number of men have been paid many times over by using these columns.

The easiest, quickest and cheapest way to dispose of, or buy new and used equipment.

Two cents per word. Minimum for one insertion $1.00. Box numbers can be had for 10 cents extra. Replies are forwarded immediately, and without additional cost.

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

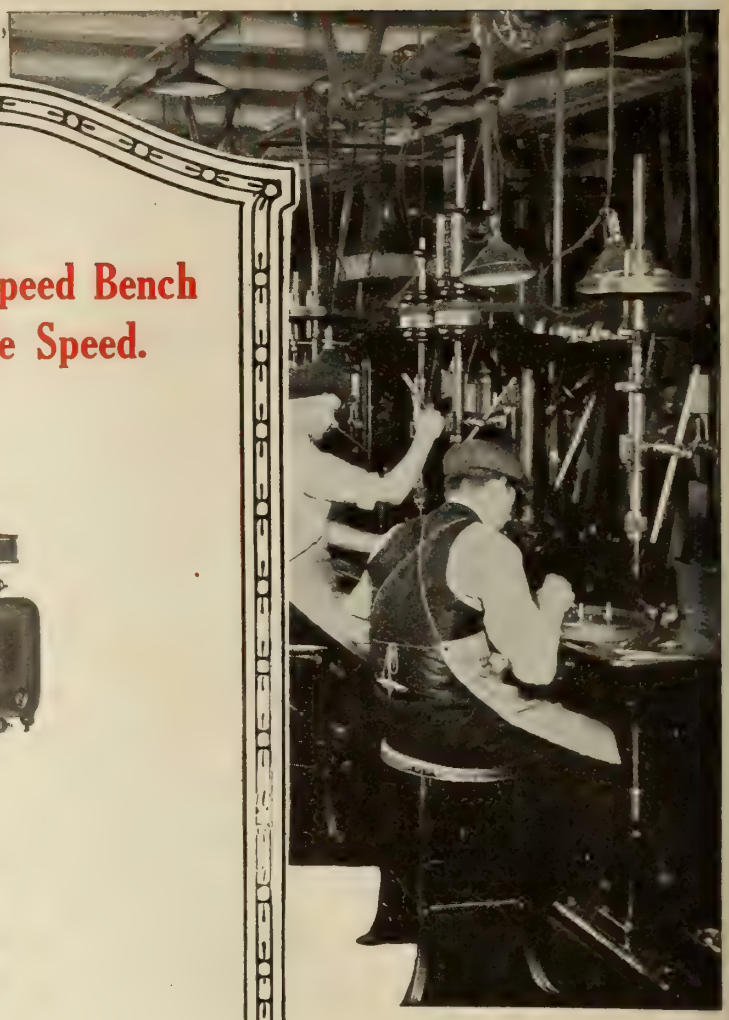
Prosperity

Is Just Around the Corner

Favorable indications of improved business mean that you will soon want every minute at your factory to be filled with a full sixty seconds of production. You will begrudge every second spent in adjustments or in overhauling machinery and belting. Remember the money-making value of reliable, efficient belting—"P.M.S" Belting!



You Need "P. M. S" Belting Now!

This is the very thing to get your transmission into reliable, dependable shape. "P.M.S" Belting is made of the toughest and strongest Sea Island cotton fabric; extra heavy, and rubberized to make it non-slip and moisture-proof. "P.M.S" Belting is proof against Heat, Cold, Wet or Dry conditions.

Merit Keeps Them On The Job

ON HEAVY tapping like this, P & W Staybolt Taps show their quality. They bite into the work with a precision and ease that makes them favorites with the men who use them.

They are not only good when new, but are heat treated and seasoned to maintain this goodness. That's why you'll find them still on the job when others "just as good" are in the scrap pile.

PRATT & WHITNEY STAYBOLT TAPS

To meet all your boiler requirements, we build P & W Staybolt Taps in five standard styles, as well as Spindle Staybolt Taps with and without threaded end and also Combined Reamer and Tap to tap continuous hole in the reamer hole of the far boiler plate.

Our reputation for precision and high quality stands behind these tools. Buy them in any of the styles and sizes listed in our Small Tool catalogue which is yours for the asking.

These taps and our complete line of Small Tools are on sale at our offices in Boston, Philadelphia, Birmingham, Rochester, Cleveland, Detroit, St. Louis, Cincinnati, Seattle, St. Paul, New Orleans, San Francisco.

Buried in the Work and Broke!

Next time a tap breaks below the surface of a large casting, don't let some make-shift method of removing it injure the thread and waste half an hour of valuable production time. Instead—

Walton it Out in a Jiffy

And save the casting.

Special analysis steel fingers of the Walton Extractor drop into the flutes of the broken tap—and grip. Then a few turns of a wrench applied to the squared end of the Extractor backs out the buried tap.

Sixty-day trial offer proves the Walton Extractor pays for itself. **Write.**

Regrinding is Vital to Continuous Truck Operation

Trucks that pile up heavy gas and oil bills, that show a lack of pep on grades or in heavy going, that smoke and knock, are laboring under faulty cylinder conditions. Such vehicles should be hauled off the road, have their power plants knocked down and a thorough inspection made of their cylinder bores.

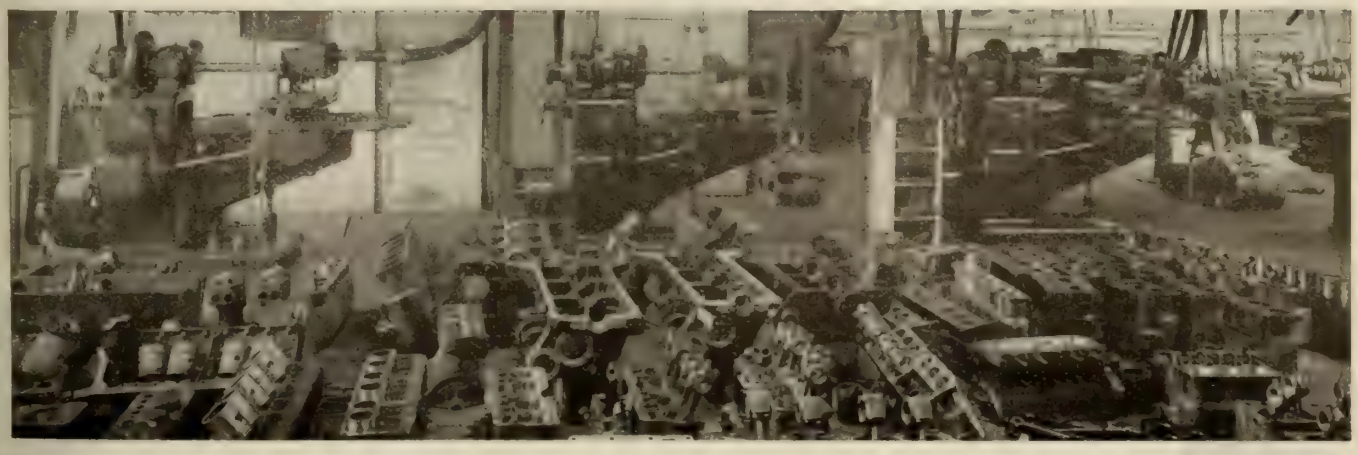
In nine out of ten cases the cylinders will be found scored and out of round.

This results in far too much clearance between cylinder walls and piston rings and permits gas to escape into the crank case and oil to work up into the combustion chamber.

Trucks are usually worked to full capacity over long shifts. They are required to make hauls that "bleed" them to their last ounce of energy.

Therefore, they should have their cylinders reground and be fitted with new oversize pistons, rings and wrist pins at least once each year.

Regrinding proves to be as economical to the owner of the single car as to the operator of the fleet.



Scores of garage, service station and small machine and repair shop owners have noted the growing demand for ground cylinder bores and have turned to the Heald Cylinder Grinder as an able aid in gaining their share of the business with astounding results.

The Heald will handle all sizes and classes of work quickly and conveniently. To-day you may have a hole 2⅜ in. in diameter by 11 in. long in a part weighing only a few pounds. To-morrow one 8 in. in diameter by 18 in. long in a casting weighing 600 or 800 pounds.

The Style No. 55 is simple, moderately priced, self-contained and has a very large capacity and range, easily taking care of all styles and sizes of blocks. Many just going into the regrinding business are purchasing this machine. Let us give you facts and figures. Establish a business that has nothing to do but grow.

ELIMINATE VALVE INEFFICIENCY

NEW AIR-TIGHT BLAST GATE

Light, Strong, Compact, Inexpensive, Quick-Acting. Threaded or Flanged connections.

Carlisle, Penna.

We are using your Blast Gate as an outlet valve on a starch tank. This tank contains a very heavy grade of starch—just liquid enough to flow. This heavy substance clogs the ordinary valve but your blast gate has, to date, given perfect satisfaction.

C. H. Masland & Sons, Inc.

Hundreds of former valve users have found the remedy by installing Rockwell New Air-Tight Blast Gates.

This wonderful control device has proved an ideal substitute for expensive, heavy, cumbersome and slow-acting gate and globe valves when used for:

Air and Gases of Various kinds

Blast furnace coal and lime dust
Counteracting back pressures
Distillation processes
Pulverized coal
Chemicals handled through pipes
Gas engine exhaust lines
Soot chutes
Starch

Present industrial conditions make it urgent that you investigate the economy and efficiency of this New Air-Tight Blast Gate. Ask our Canadian distributor for Circular 210-T.

Herring-bone Cut Gears

The Highest Type of Gear Drive

GEAR DATA FOR YOUR NOTE BOOK
Cut this out,—more coming later

"DON'TS"—ON THE USE OF GEARS

From The Hamilton Gear and Machine Co., Toronto

Don't run two soft, low carbon steel gears together. They will not wear well. Use harder steel or two different metals.

Don't use moulded or cast tooth gears for any but the slowest speeds and roughest surface. Use Cut Gears.

Don't let oil or water on a rawhide pinion. For damp or oily places use an extra quality of hard white or grey fibre.

Don't use cast iron pinions. A pinion tooth is weaker than a gear tooth of the same metal. Therefore use a tougher material for the pinion.

Don't use brass for gears. A few cents a pound more will give you bronze, which is more than double as good. Use No. 1 Government bronze:—80% copper, 10% tin and 2% zinc.

Don't forget that the Hamilton Gear & Machine Co. has the only real gear shop in this country; that their modern plant with heavy, up-to-date machinery is at your service in any emergency. Use telegraph or long distance 'phone.

Don't run gears unguarded, if there is any possible way to put a shield around them. This is to protect the gears from damage, whether you value your fingers or not.

Don't omit details when asking prices or placing orders for gears. The fuller the information the better price and delivery you will get.

Write for Quotations

Hamilton Gear & Machine Co.

Examples Where Vertical Milling Saved Money

Suitable Fixtures Facilitate Production—Multi-Tooth Cutters Replace Single Point Tool—Particularly Adapted to Die Sinking—Special Attachments for Continuous Milling.

By J. H. MOORE

AMONG MANY other production tools, the vertical miller has proved itself to be of exceptional value especially on duplication work. This statement must not be misunderstood, because, a vertical milling machine is likewise useful on general manufacturing work, but where the operation can be plotted out ahead, a suitable fixture made, and so on, it is in such cases that the productive possibilities of the machine show up to best advantage.

The variety of parts which can be handled is surprising, and in many cases, vertical milling has superseded other methods of machining. For example Fig. 1. Here we see a vertical miller machining an electric motor bracket. Some might consider this a job for boring mills in fact it was first of all completed on a boring machine, but the time saved by using the vertical miller proved conclusively the wisdom of finishing the work in the manner shown.

These frames are cast steel, and must be surfaced where they bear on the laminations, as well as bored for clearance. When finished on the boring mill, the full capacity of machine could not be used, as the interrupted feed prevented using a heavy cut. Owing to the tendency of the work to spring away from the tool, two cuts were necessary to get a flat surface. The complete operation, facing bracket, and finishing of bore, took 55 minutes, this time being considered excessive.

By using the vertical miller, the single point boring tool has been replaced with multi-tooth cutters, and although the amount of metal removed is much greater, the pressure on the work, tending to spring the piece is very much reduced. The pressure of the cutters acts towards the center of the piece in the line of its greatest strength, and one pass of the cutter over the work covers the surface and produces a flat job. Production time has been cut almost in six, for in place of 55 minutes, the time is now only 9½ minutes. The operator never requires to change his position to shift from the cutting feed to rapid traverse, as the feed box is at front of machine. Although shown on this particular operation, the same general scheme of handling can be applied to innumerable heavy profiling jobs such as gear boxes, covers, segments, etc.

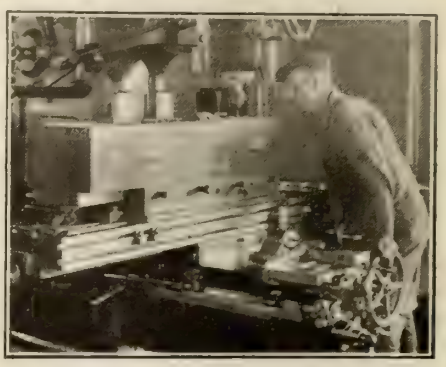

Fig. 3.—Intricate Die-Sinking on Vertical Miller.

Milling Wedge Block

Cutting production time in a piece from 60 to 40 minutes is well worth while, and the work shown at Fig. 2 holds up to this record. Previously the wedge block illustrated was finished on a planer in a railroad shop, and the oper-

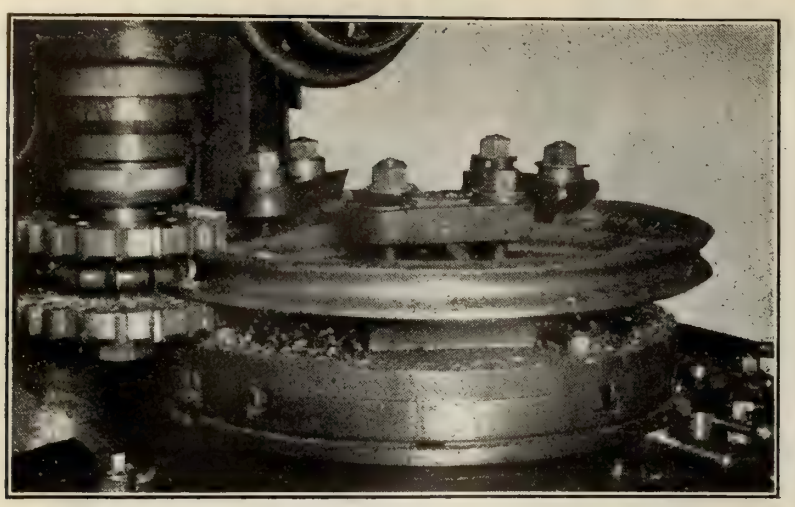

Fig. 4.—Gang milling a sheave wheel.

ations were planing bottom and inside. At present the part is milled in two settings, the bottom surface being finished first. As will be noted two standard steel vises are used to hold the block, and the piece is lined up parallel with the table by means of a surface gauge. The photograph shows all other particulars.

For Die Sinking

To prove the previous statement that vertical milling machines can be used on general work, refer to Fig. 3. This shows an intricate operation of die sinking being performed, and any mechanic who has attempted work of this nature knows the need of accuracy and ease of control. In the illustration shown the machine is so arranged that both the longitudinal and cross feed are handled by the operator without moving. As can be noted, he is at all times in a position to watch the operation carefully. Die sinking, of course, is merely one of the general uses for such machines.

Continuous Milling

There is also that field known as continuous milling, and the remaining illustrations deal with this type of operation. This method is used where high production is desired, and Fig. 4, shows an interesting gang milling operation on a steel sheave wheel. The cutters used are as follows. The outside diameter is form milled, while the two sides are faced. The side cutters are 8 in. diameter, while the form cutter is 6 in. diameter. A feed of 3 in. per minute is used, and the cutter spindle revolves at 28 r.p.m. Usually about ¼ in. stock is removed, and the time on each wheel is 30 minutes. Some might consider this a lathe job, but the milling time has reduced cost considerably.

Another clever arrangement is shown at Fig. 5. In this case the inside faces of universal yokes are being milled, and production is around 160 pieces per hour. Two 7 in. staggered inserted tooth cutters are used, and the fixture shown has 36 stations. When a high rate of production is necessary, value of fixture as depicted is evident. There is nothing elaborate about it, and yet without the aid of quick loading the productive qualities of the machine would be handicapped. Whenever work of the nature illustrated is being contemplated, it pays to spend time and thought on the design of fixture used. A little extra money and thought expended, will often increase production to a surprising extent.

At Fig. 6 is shown the milling of differential gear housings. These castings weigh approximately 40 pounds and are made of malleable iron. Formerly 9 per hour was the production figure, but using the machine and fixture illustrated, 15 per hour can be machined. There is nothing elaborate about the fixture, for it merely consists of support blocks, with quick acting clamps. A slight slackening of the nut, and the clamp slides back by means of the slot shown, and as the clamps are on an angle, they slide back automatically the moment the nut on holding down bolt is released. A large inserted tooth cutter is used, this being the best type for such work.

The remaining illustration Fig. 7, shows how the continuous miller can be made still more productive by the addition of another spindle. On certain classes of work, two surfaces of about the same level, and yet too far apart to be milled by one cutter, must be machined. When quantity warrants the investment, a two spindle machine is a good thing, for it reduces labor cost, and handling time, increasing of course the number of pieces completed per hour.

Usually a simple fixture is all that is necessary to mount on the work table, and the operation shown at Fig. 7, bears this statement out. There is nothing intricate in the fixture illustrated, and yet the rods are quickly and accurately located. Each clamp holds two rods, being worked on the eccentric principle, while at large end of rod, one lug goes up against a tool steel locating block, set into the ordinary steel filler between stations, while another locating medium operated from the screw A, tightens both rods at the same time. Straddle mill cutters are used, these having inserted cutters. The rods milled on this machine vary in length from 11 in. to 14 in., and production likewise ranges between 65 to 75 per hour.

While these illustrations barely scratch the surface of the possibilities of vertical milling, they at least give a few applications which may suggest other operations to readers, who at present may be finishing parts in some other way. For example, the planing time on a trailer spring saddle guide was 40 minutes, yet by simply holding this piece in the vise on a miller table, and using a regular cutter, the operation time was cut down to 28 minutes. Two vises were placed on the table, this allowing the operator to unload and load, while the other piece was being finished. Two cuts were taken in the 28 minutes, as the parts were made from cast steel and

Planning and Installing Effective Lighting

Proper Distribution of Illumination—Adapting Existing Equipment to Best Advantage—Allowance Made for Ageing of Lamps —Surfaces That Reflect Light.

By JOHN T. SCOTT

THE INTENSITIES of illumination required for different classes of work were outlined in the previous issue of Canadian Machinery. We will now consider the methods for planning an installation.

The requirements of any satisfactory industrial lighting installation are:

1. Sufficient light on all parts of the working area.
2. Moderate light on adjacent areas and on the walls.
3. Freedom from glare or glaring reflection.
4. A system, simple, reliable, easy to maintain, and of low operating cost.

The conditions usually presented are two:

1. Where the building has not been wired before, or where, if wired, the plant manager is willing to rearrange the outlets. Here the greatest freedom is allowed in planning the installation.
2. Where no change or addition is to be made in existing outlets. In this case we have but to decide upon the proper type and size of unit to replace the present fixture.

Factory interiors are usually divided by columns into bays or rectangles of uniform size, as shown in Fig. 1, and such bays afford a convenient starting point in determining the location of the lighting units. It is desirable that the lighting units be symmetrically spaced throughout the whole of an interior and this will result if the units are properly spaced in each bay. Furthermore, a correct lighting design presented in terms of individual bays can be readily extended throughout a plant of only a few or of many bays.

Planning the Installation

In order to determine the requirements of the installation the following procedure is generally adopted.

1. Determine the foot-candle illumination required.
2. Calculate the floor area and number of lighting units required.
3. Determine the spacing of the outlets and mounting height.
4. Ascertain the size of Mazda lamps which will provide the foot candles required.

Let us now figure out the illumination required by a machine shop doing a medium class of work. We will decide upon 10 foot candles for illumination at the working plane. Now make a diagram to scale of the floor area of the room, which is say 60 ft. by 200 ft. The spacing of the outlets will in part be determined by the mounting height. Measure the ceiling height and refer to the following table for permissible spacing distance.

Mounting Height of Unit			
Above Plane of Work	Above Floor	Permissible Distance Between Outlets	Distance Between Outlets and Walls
4	6½	6	3
6	8½	9	4½
8	10½	12	6
10	12½	15	7½
11	13½	16½	8
12	14½	18	9
13	15½	19½	9½
14	16½	21	10½
15	17½	22½	11
16	18½	24	12
18	20½	27	13½
20	22½	30	15

Table of Spacing and Mounting Height

Figures are for feet. Plane of work is assumed to be 2½ feet above flor. When work on a plane higher or lower than 2½ feet, then work from first column.

Let us take a ceiling height of 18 feet and decide to give a drop of 18 inches to the unit. This gives us a mounting height above the floor of 16½ feet and 14 feet above the working plane, with a permissible spacing distance between units of 20 ft. Our plan will enable us to mark out 3 rows of 10 units, 20 ft. apart, with an outside distance of 10 ft. from the walls, providing a total of 30 lighting units.

If the units are mounted as close to the ceiling as possible, a wider spacing is permissible, fewer units are required, and the cost will be less. An allowance of one foot is usually necessary to provide for the drop of the reflector from the ceiling.

Having determined the permissible spacing proceed to locate the outlets on the diagram of the floor area. Locate the units as nearly symmetrically as possible without appreciably exceeding the permissible spacing for uniform illumination. The distance between the walls and outside row of outlets should not exceed one half the spacing distance; or above one third the distance if benches are near the wall. After the outlets have been located on the plan, the lamp size to be used may be ascertained by the following method of calculation:

A. Area in sq. ft. per outlet

$$= \frac{\text{Total floor area in sq. ft.}}{\text{Number of outlets}} = \frac{60 \times 200}{30}$$

$= 400$

B. Lamp lumens required per sq. ft.

$$= \frac{\text{Foot candles x Dep. Factor}}{\text{Coefficient of Utilization}} = \frac{10 \times 1.3}{60}$$

$= 22.$

C. Lamp lumens per outlet

$= A \times B = 400 \times 22 = 8800$ lumens

A 500 watt Mazda gas-filled lamp has a light output of nearly 9,000 lumens, therefore our installation will consist of thirty 500 watt lamps. This lighting will give us an illumination of approximately 10 foot candles.

An arbitrary use was made in the above calculation of two figures which require explanation. The depreciation factor is a safety factor or allowance made for ageing of lamps, dirt, dust and deterioration. For fairly clean conditions use a factor of 1.3; for dirty locations where cleaning is infrequent use a factor of 1.5. With regard to the coefficient of utilization, this ranges from .46 for medium size areas to .69 for large areas, based on using a standard metal dome reflector. Fairly safe calculations may be made for all conditions with a factor between .50 and .60.

Colored Surfaces

A material consideration that should not be overlooked is the matter of painted surfaces, walls and ceilings. These have an important bearing on both natural and artificial lighting. Dark colors will absorb light and so lessen the useful illumination. White, and very light colors like stone, ivory and very light

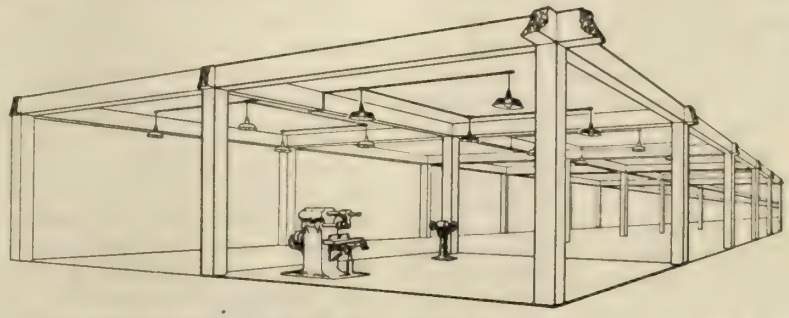

Fig. 1.—An industrial interior can usually be divided into sections, or bays, by which the lighting units can be located in the design of a modern lighting system. Sometimes, where no structural features suggest a natural division into bays, it will be necessary to sketch a floor plan and to draw in imaginary bays of uniform size, the size depending upon the grouping of machines, benches, etc. These bays should be chosen as nearly square as is practicable. In the interior shown, beams divide the interior into 20 x 20 ft. bays; 4 units are symmetrically spaced in each bay.

Author is engineer in charge of standardization work at the Sunbeam Lamp Works.

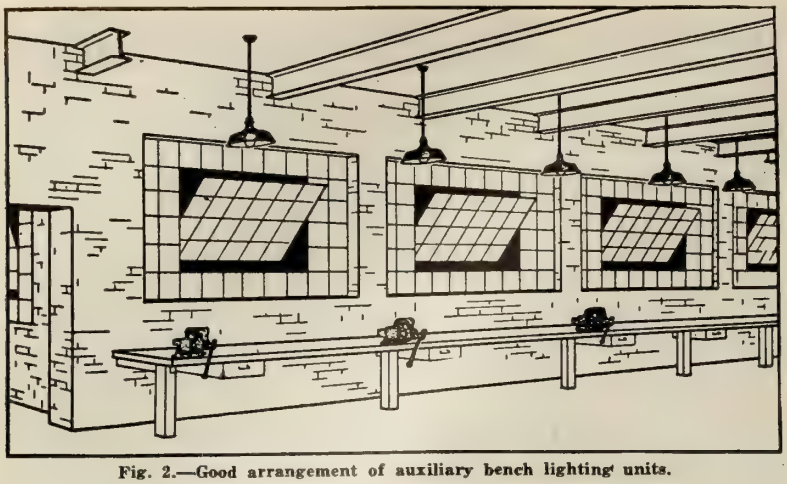

Fig. 2.—Good arrangement of auxiliary bench lighting units.

gray will reflect the light and prove a useful aid in illumination. Matt or dull surfaces will be better than oil or glossy, since there will be no undue brightness or reflection.

Bench Lighting

Where more units are employed than one per bay, bench lighting can be adequately cared for by shifting the outside rows of units nearer to the walls along which the benches are placed. This means, of course, that the spacing distance between the outside row of units and the next is greater than it should be, and the illumination at points between the two rows is correspondingly reduced. However, since this area of low illumination usually covers the aisle between the benches and the first row of machines, the effect is usually not serious. On the other hand, where only one unit is employed in each bay, best practice usually requires auxiliary bench lighting units. A typical good arrangement of auxiliary units is shown in Fig. 2.

The use of 100 watt, bowl-frosted, Mazda C. lamps in R. L. M. standard dome reflectors, spaced 8 ft. apart and mounted 6 to 8 ft. above the bench tops will provide an average illumination on the bench of about 6 foot candles; this is of course in addition to the light received from the general overhead system. The use of 150 watt lamps will increase the intensity of illumination to about 10 foot candles. The distance between the units and the wall will be governed by the width of the bench. The unit should be located so that the lamp is out from the wall about equal to the width of the bench. Where it is possible to mount the units about 2 ft. higher, the spacing may be increased to 10 ft. apart.

Should any reader have any difficulty in using the methods of calculation outlined above, or meet with any special problem, the writer will be glad to cooperate by offering helpful suggestions. The next and concluding article will deal more fully with choice of lamps and equipment, and conditions of use.

Economy of Cork Inserts

By W. F. Schraphorst

Copyright, by W. F. Shraphorst

This is an important topic that has not been written about or discussed to such extent as have other transmission devices. Why this is so is unexplainable. It is a worthy subject because cork insert is to stop all avoidable belt factor as the other devices that stop belt slip. The principal functions of the cork insert is to stop all avoidable belt slip. In doing this considerable coal and money may be saved.

Thus where 2,000 tons of coal are burned per year where coal costs $9 per ton, and where the over-all belt slip is 8 per cent., the cost of the belt slip in terms of the coal pile is $1,440. To compute the cost of belt slip it is first necessary to find the percentage of slip. That is, if a driven pulley rotates only 95 times, whereas it should rotate 100 times, the percentage of belt slip is 5 per cent or,

$$\frac{100-95}{100}=5 \text{ per cent.}$$

Then multiply the determined per cent. of slip by the number of tons of coal burned per year, and then by the cost of the coal per ton. Thus we have

(2,000 x $9 x .08= $1,440.)

the yearly cost of belt slip.

To arrive at the actual and accurate cost of belt slip is not easy, however. It is plainly more than $1,440 in such a plant as above, because coal is not the only thing that is lost. The belts wear out more rapidly where ther is slip than where there is no slip, and the cost of this slip can be approximated.

Let us assume, just for an example that with cork inserts a plant manages to keep its belts a-going for 10 years. The first cost, then, is $500 per year. Without cork inserts the belts wear out in eight years, and the average cost is $625 per year. This would mean a saving of $625—$500, or $1,250 in 10 years. As these figures may not apply to every plant this formula may be used and the reader can substitute his own conditions.

Dollars saved with cork inserts from belt cost standpoint only equal

$$(No.—N)\ K$$

$$N$$

where Nc=life of belt in years with cork inserts;

N=life of belt in years without cork inserts;

K=first cost of belt in dollars.

The cost of lost product must also be considered. The value of cork inserts appears here again, and the problem can be approximated mathematically. Let us take, for example, the above plant where over-all belt slip is 8 per cent. and where the output should be worth, without slip, $2,000 per day. With 8 per cent. slip it is evident that the machines are running 8 per cent. too slow and the product is, therefore, diminished by 8 per cent. Hence the daily output is approximately

$2,000—($2,000 x 8%)=$1,840 instead of $2,000.

To make the formula clearer, and to enforce this cost on the mind of the plant owner, I have thrown it into this form:

Dollars output lost per day=

$$\frac{D}{1—S}—D$$

were D=present daily output in dollars;

S=per cent of belt slip.

Thus, if your present daily output amounts to $1,500, and if your over-all belt slip is 10 per cent, we have, after substituting in the formula

$$\frac{1,500}{1—.10}—\$1,500=\$1,667—\$1,500=\$167.$$

One hundred and sixty-seven dollars lost per day is considerable and may mean the ruin of a small plant, unless discovered and rectified. This "product loss" is often saved by speeding up the driving engines or motors to the extent that after belt slip is deducted the final speed is what it should be anyway. That method is better than none at all, but it is not the best practice. The best practice is to eliminate all belt slip.

Thus comes the cost of defective product. Where belt slip is permitted, the product frequently suffers on that account. The loss cannot be figured mathematically, because it is too uncertain. It may vary from a trifling to a very serious amount. To reduce this loss to the minimum, belt slip must be completely eliminated. By so doing, all machines are driven by steady speeds. There is no bunching here and thinning there. Product is uniform, day in and day out. Such is the ideal state as regards speed, and the value of cork inserts is further emphasized.

R. P. Ross & Co. of Sudbury, have secured contracts on behalf of the Standard Steel Construction Company Limited, for all the construction steel work on the Copper Cliff school and the Salvation Army citadel, Sudbury.

Characteristics of the Different Forms of Gears

Classification—Continuity of Tooth Action—Advantages of Herringbone Form—Moulding Generating Process—Conical Features of Bevel Gears.

By CHESTER B. HAMILTON, Jr., B.A.Sc.

IN THE April 13 issue the author covered the different materials of which gears are constructed and the process of heat treating steel gears. The present article goes still further into the manufacturing of the different types of gears and their various applications.

The whole object of gear work in general is to transmit motion and power from one revolving axis to another revolving axis. There are special cases which appear superficially to contradict the general statement, but on analysis they are all resolvable within its limits. For example, a straight rack is a segment of a gear of infinite radius, and a fixed or stationary gear in a train must at least have relative motion, with regard to the other members of the train. It is evident therefore that a classification of gears according to their axes will be a basic classification.

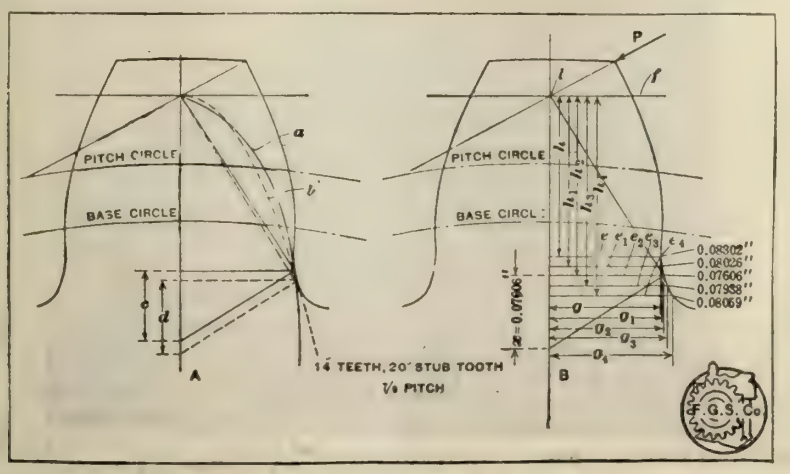
The separation of the classes is not quite absolute, in that a few gears may be used in two different classes. A spur gear may be matched with a worm of equal normal tooth dimensions by setting the worm askew at a suitable angle. A pair of helical gears, meant to run in mesh on parallel shafts, may if helix angle is high, in the neighborhood of 45 degrees, be each operated as a worm by supplying a suitable mate. It is to be noted that these are both cases of point tooth contact and high sliding action.

The great majority of gears have their shafts parallel and are of cylindrical form. This class includes the spur, the helical and the double helical, each in both external and internal form. The spur has all its teeth parallel to the axis. The helical, and the double helical, have teeth formed along helical curves on the surface of the imaginary pitch cylinder. The double helical is merely two helical gears of right and left hand, but otherwise identical, mounted on the same shaft. The helical gear is frequently miscalled spiral. The error is obvious on considering that the spiral is a curve developed about a centre point in a flat plane, while the helix is a curve wrapped about a cylinder.

The true spiral gear is exemplified in the scroll that operates the jaws of the ordinary universal scroll chuck used on lathes. In this example the scroll meshes with a rack on the back of the jaw. The double helical gear is the modern development of the herringbone gear, and is frequently called by that name. A more remote ancestor is the hook or stepped gear, which is a series of narrow faced spur gears, each set an equal fraction of the pitch ahead of its neighbor, so as to improve the continuity of tooth action, and so give smoother rolling motion. This quality of all the helical family of gears is very important and permits them to be run at enormously higher speeds than is possible with even the best of spur gears. They are used exclusively in the high speed and high ratio reduction sets for reducing the speed of steam turbines, both on steamships and stationary industrial drives.

Double Helical Gear

The double helical will carry considerably more load than the corresponding spur gear, for two reasons. First, its smooth action and freedom from shock permit a smaller apparent factor of safety to be used with the same real safety in result. Second, the helical arrangement of the teeth ensures that there are always some teeth in every stage of coming into and going out of mesh, and some teeth fully meshed and bearing at the pitch line. Therefore there is never a time when all the load is being applied at the tip of the pinion tooth, which is the critical instant with spur gears. The advantage of the double helical over the single helical form is the elimination of end thrust. The double helical gears are usually made with a helix angle of 23 deg., except the very high speed turbine gears which often have high angles, up to 45 deg. The single helical gears are usually made with an angle as high as possible without serious end pressure, which is about the angle of friction. Fifteen deg. is one standard widely recognized.



Internal Gears

The internal gear while apparently a spur or helical with its teeth turned inwards, has several wide differences, especially in tooth action. The development of the internal gear has been slow on account of difficulties in producing it accurately. As long as cast gears were in vogue the internal held its own, but to cut it was a serious problem. The rotary cutter or milling process was at a disadvantage on account of necessity of providing a special cutter head with a very awkward drive for the machine, which operated at low efficiency, and also the clearance for the cutter after passing through the tooth hampered the designer. To do a correct job special cutters with convex curves were required, but as the ordinary No. 1 range cutter intended for cutting large gears and racks was commonly used, the results were poor and internals come to be avoided for small and medium work. The Gleason spur gear planing machines which operate on the templet principle, do produce good internals in large sizes. It was not until the invention of the Fellows gear shaper, however, that the internal gear in small and medium sizes could be produced of high quality at low cost. It is now produced in spur, helical and double helical on this machine, which operates on the moulding generating principle.

Distinct Features

The internal gear differs from the external in a number of ways, which influence the tooth action, mostly to its great advantage. The addendum of an internal gear is the distance from the pitch line inward to the tip of the tooth, and the dedendum is the distance from the pitch line outward to the root of the tooth. The base circle of an involute gear is the circle from which the involute

Author is President of the Hamilton Gear and Machine Co., and a member of the American Society Mechanical Engineers; Engineering Institute of Canada; Society of Automotive Engineers; American Gear Manufacturers' Association, Steel Treating Research Society; Standardization Committee of A.G.M.A.; Associate Member of American Institute of Electrical Engineers.

Two methods of determining weakest section of gear tooth. A shows method of constructing a parabola by drawing an irregular curve. B shows method of calculating weakest section of tooth.

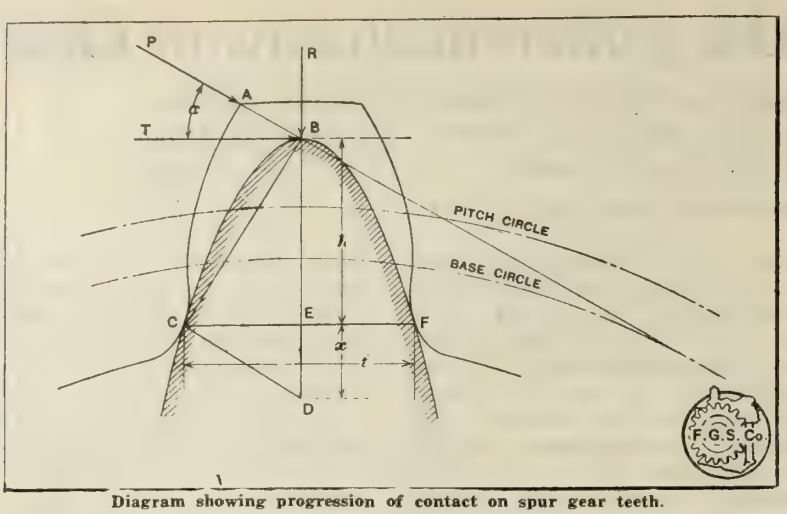


Diagram showing progression of contact on spur gear teeth.

tooth curve is developed by the unwrapping of a tangent which contains a describing point. Therefore the base circle is always of less diameter than the pitch circle. In the case of the internal gear the base circle lies in the addendum, instead of in the dedendum, as with the external gear. On account of the internal gear curving toward the pinion, instead of away from it as an external gear does, the line of action is much longer.

It follows that the engagement of the gear and pinion tooth takes place in a much more gentle fashion, greatly reducing shocks. There are more teeth in mesh at one time so that even with very small pinions the operation is satisfactory. It may be readily demonstrated graphically that the amount of sliding between the surfaces of gear and pinion tooth is much less less with the internal than the external, comparing cases where all other elements are equal. Even with the most perfect generated involute tooth curve the pure rolling motion exists for only an instant as the pitch lines of gear and pinion roll over each other. For all other phases of contact there is an element of slide added which increases with the distance from the pitch line.

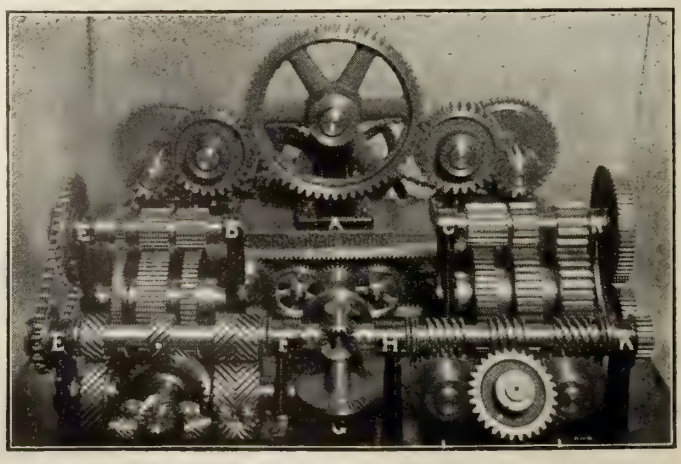
Element of Interference

As to the question of interference, there would be more of this in the case of the involute internal if the uncorrected theoretical form were used, not that the involute theory does not work out in practice, but due to the fact that the tips of the gear teeth are the part below the base circle, not above, and theoretically are not curves at all, unless corrected in some way. This is done empirically in the case of the formers of the Gleason planer. In the Fellows system the fact that the cutter works on the moulder generating process saves the situation automatically. The straight flanks of the cutter tooth, below its base circle, roll in mesh with the gear tooth it is forming and shave off that portion of the tooth next the inner tip which would interfere with the flank of the pinion tooth.

Interference between the tip of the pinion tooth and the flank of the gear tooth is prevented just as in external gears by a suitable combination of working depth and pressure angle of tooth. With the 20 deg. stub tooth system the limit is reached when the difference between the number of teeth in the gear and those in the pinion is seven. With the 14½ deg. generated tooth of full Brown & Sharpe standard depth the limit is a difference of twelve teeth. With the 14½ deg. tooth, not generated but formed or planed from templet, fifteen teeth is a safer margin to allow between gear and pinion sizes.

Mitre and Bevel Gears

The second great class of gears is those having their axes in the same plane but at an angle to each other, so that they will intersect if produced. This class covers the bevel gear and all its variations, except the skew bevel gear which is truly not a bevel at all but a hyperboloid.



The distinguishing characteristics of all gears of the bevel class is that they are conical in form and conical in action. This is independent of the angle of the axes, which may be greater or less than the usual right angle. It is independent of the pitch angle, which may be, theoretically almost anything, and is limited only by practical ability to machine the teeth of the gear. It is independent of the style of the teeth, which may be straight and converging on the cone centre; or may be spiral curves, about that centre, laid out on the pitch cone surface; or may be arbitrary curves, as a segment of a circle, in the case of the Gleason so-called "spiral" bevel; or may be a combination of two almost straight lines, as in the Citroen gear, so as to produce a herringbone effect. All considerations of bevel gears must be based on a knowledge of the pitch cones of the pair, whose apexes coincide and whose surfaces are tangent.

Angle of Axes

Taking the other features in turn, first consider the angle of axes. Practically all bevel gears have shafts set at right angles. Those at other than the right angle are sometimes called angular bevels. They do not differ in form from any other bevel. Their ratio is determined by the pitch diameters which are proportional to the sines of their respective pitch angles, for the distance from the cone centre to the point of tangency of pitch circles is the common cone line. A crown gear is a bevel which is flat, that is, has a 90 deg. pitch angle. Its pitch cone is then a disc with the point of intersection of axes, or cone centre, at the middle. An internal bevel has a re-entrant pitch angle of less than 90 degrees. The teeth are of different form, having concave curves. There are limits to the size of the mating pinion, just as in the case of the internal spur.

Pitch of Bevel Gears

The pitch of any bevel gear, unless specifically stated otherwise, is the pitch at the large end of the teeth. The blanks are turned with the surface at the big end of the teeth at right angles to the pitch angle, or the pitch line to cone centre. This surface if extended backward or inward to the axis would form the imaginary back cone, and the distance from the pitch line to the apex of the back cone is the back cone radius. This is important in considering tooth forms, though it does not enter into every day gear production. The forms

Showing an interesting assembly of different types of gears.

of the teeth are considered as they would be developed on a plane from their respective back cones, and all the tooth action corresponds to the action of two spur gears of radii equal to the radii of the respective back cones and revolving about their apex points. It is seen then, that the tooth form of a bevel gear is not the same as a spur gear of same pitch and pitch radius, but rather a spur of same pitch and a radius equal the bevel gear's pitch radius divided by the cosine of the pitch angle.

In the case of the crown gear the back cone radius is infinitely long and the tooth curve becomes a straight line. In the case of the internal bevel the back cone centre is in front of the gear, and this negative position is one of the causes for the tooth curves being concave in which they again resemble the spur internal. The internal bevel is of little or no practical value, while the spur internal is a very useful, efficient and highly developed class of gear. The consideration however, of all the different possible cases of the bevel is essential to a full understanding of the interrelation of its different parts. The truly flat crown gear is a practical gear, for angular mounting of course, but is rare. What are commonly called crown gears, such as in the rear axle drive of automobiles, or under boring mill tables, are merely any bevel gear which closely approaches 90 deg. pitch angle.

Origin of Bevel Gear

The history of practical cut bevel gears on this continent would be the story of the efforts of two men who worked independently at the problem. William Gleason, of Rochester, invented and built bevel gear planing machines that worked on the templet principle, the same as his spur machines. In fact, some of them cut either spurs or bevels. Hugo Bilgram of Philadelphia, invented a bevel gear generator which used straight edged tools and worked on the moulding generating principle. The tools traveled in a path, relative to the work, which made them play the part of teeth in an imaginary crown gear meshing with the gear being cut. The work of this machine was very fine, and intrinsically there is no doubt it is superior to the Gleason templet machines.

Hugo Bilgram, however, would not sell these machines, but tried to have all the high class bevel work in the country sent to his shop. This was a mistaken policy even in the days before automobiles were invented. The Gleason Works sold their templet machine over the whole world, and it was and is so satisfactory that, though William Gleason and his sons developed a bevel gear generator aimed to beat the Bilgram generator, it was not found commercially necessary to bring it out for a number of years. Then, to meet the call for better gears for the automobile and finer machine trade, it was put on the market and was found to not only equal the Bilgram quality and theoretical perfection, but to have much greater productive capacity.

Manufacturing Difficulties

The true spiral bevel gear is not a practical form on acount of difficulty of manufacture. Andre Citroen, of Paris, France, developed a method of making herringbone bevels, using an end mill of special profile to form the teeth, along the same general line as his well known spur gear process. A compromise spiral gear was used for several years by the Packard Company, using an altered form of Bilgram machine. The teeth of the gear were planed, not toward the cone centre, but toward a point off to one side. The teeth of the pinion were made in a similar way but on the other hand, the offset being negative. The objects of these and many other attempts along the same lines were two fold,—strength, but quietness—in the case of Citroen, strength, but in the automobile trade mostly quietness. When the automobile had been perfected to the point where all the rest of the machine made less noise than the bevels in the rear axle, it became evident that something radical must be done for that member. In shops turning out good bevels, as much as seven per cent. of otherwise perfect product would be scrapped for noise. One prominent maker of high class cars even went to the extent of using a worm drive in the rear axle of touring cars for several seasons.

(To be continued.)

TAPPING SQUARE THREADS IN STEEL

By Jack Homewood

The tapping of square threads in steel is no snap when the diameter of the hole is small in comparison to the pitch of the thread and also when the piece to be tapped is long. Many years ago when the writer was eager for fame, he dropped into a small manufacturing town and landed a job. In this plant they were making small parts and square threaded nuts of the above peculiarities. Being young and enterprising like all the others, it behooved me to scan the field of endeavor to see where I would start first in making a clean up. Not being eager to await my demise before having a monument erected in my honor, I proceeded to lay the foundation of one of my own design and manufacture, embodying all the nice things that suit my taste.

Having just arrived from Cleveland and also having tapped ¼ in. 20 threads in ⅛ in. brass plate years before, my being was horrified when to my chagrin a youth before me was tapping out some nuts as I have already commented upon, using anywhere from fifteen to twenty taps. The apparent inefficiency was evident; such a waste of time and lard oil was too much for me to stand.

Knowing that the cost of the nuts was excessive and knowing that I was new blood in the institution, and that I had come from an enterprising and prosperous city, the works manager granted me an interview which included the mechanical engineer and the shop foreman, Bill. As I unrolled the sketch that I had carefully made up, of a single tap which first started as a V-thread, then to an Acme and finally to a square form, I had the same feeling that overcomes a young lawyer as he is about to make his first appeal in court. The problem of tapping those nuts had been a knotty one for years, and here was I, only a youngster aside from the rest, with an idea that was going to turn the shop upside down.

As I proceeded with my plan the manager leaned back in his chair and sized me up and down greatly to my satisfaction; he was admiring me. The more he looked at me the wider open I turned the valve. Mustard gas wasn't known in those days but whatever the ingredients were, it had the same effect. Bill, who had in past years worried, dreamed, thought, reflected, cogitated, argued, experimented and failed, slowly receded in his towering stature as I grew in power. My argument was concluded very forcibly as I inquired, "Gentlemen, what do you think of my plan?"

The mechanical engineer looked at the manager; he in turn looked at Bill who by now had slipped his hands into his pants pockets and tramped back and forth wearing that smile of doubt, "It can't be done, it can't be done," was all Bill would murmur. One glance at the cost sheet and the manager's reply syn-

Practical Application of Precision Instruments

Construction of Different Gauges—Improved Designs Increase Efficiency—Reducing Weight of Larger Sizes—Combining Blocks for Checking Dimensions—Testing Micrometers for Wear

By H. ALTON

IN CONTINUING the study of the use of precision measuring instruments, the broad field of such work makes it only practical to discuss the apparatus, methods, and practices which are the most common, or have some outstanding feature of general interest. The science of precision measuring, as we have seen, goes hand in hand with the modern development of shop practice, namely quantity production and interchangeable manufacturing. Standardization of product has been made possible largely through the fact that precision measuring can be accomplished in the manufacturing shop through the medium of special gauges. One cannot separate precision measuring from a system of gauges, because gauges are the commercial evolution of precision measuring instruments, produced for practical use.

Gauges are classified in several general ways. The classification as to uses contains three subdivisions namely, shop gauges, inspection gauges and reference gauges. These applications are self-explanatory. The shop gauges are those that are used by the operators on the machines to verify the work as it is produced. They check an error practically as soon as it occurs and eliminate the continued production of faulty pieces. For this reason time and material are saved on many occasions with resultant monetary savings. Generally speaking, shop gauges are designed with somewhat smaller tolerances than are the other classes of gauges which are used to check the same dimensions. There are two principal reasons for this, first is that shop gauges are subjected to the most severe conditions and often receive abuse, both conditions conducive to wear and possible error. Secondly, if the shop gauges permit a smaller tolerance range it is all the more reason to believe that when the product is subjected to the inspector's gauges that a greater per cent. of it will be acceptable. It is always well to have this slight margin of safety.

The inspection gauges are usually made to have a slightly less range between the high and low limiting dimensions than the reference gauges for practically the same reasons that the shop gauges vary from the inspection gauges.

Other classifications of gauges can be made from the features of their design, quite apart from their various functions. Many simple gauges are made from flat steel. Small snap gauges, profile gauges and such gauges for gauging small parts lend themselves to this method of design and manufacture. Sometimes many slots are cut in one piece of flat steel for gauging several dimensions. As this type of gauge is solid and non-adjustable several developments have been made to overcome wear. Removable inserts have been placed in the slots and also several gauges have been tied together by small plates. Both of these arrangements have been followed to a considerable extent.

Another simple type of gauge is the ring gauge. The name of this gauge indicates its design. It is simply a ring of solid steel for gauging cylindrical work. This type of gauge is not usually made with high and low limits in the one piece. It is practically always either high or low.

Another common type is the snap gauge, and it is made in either the solid, adjustable, or limit designs. For internal work, the three point contact, or star gauge is often used. Several types of gauges have incorporated in their design, indicators, which are capable of registering high and low limits as well as the exact intermediate dimension. A step further is sometimes found in gauges with dial indicators. Apart from these general classifications there are literally thousands of special gauges for use on an equally varied line of product.

Trussed For Snap Gauges

A new form known as the truss snap gauge has recently been devised which has some interesting features. These gauges are adjustable and are of the limit type. They are cast iron and the various portions are in tension and compression similar to the members of a roof truss.

The open design is, of course, much lighter than a solid frame and it is claimed that it is much stiffer and less liable to deflection. The outer rib with its broken line gives a peculiarly reliable and grateful grip to the fingers, even when oily. The anvils have a rather unique adjustment. There are two opposed headless set screws pulling in opposite directions similar to the conditions existing in the screws of an independent lathe chuck. By pulling one screw against the other the finest adjustment, positive in either direction, is easily made. When both are tight the anvil is secure against "shake" in any direction, cannot be jarred loose, and is readily sealed. The holes in which the anvils work are accurately line reamed and the anvils lapped square. The gauge is equipped with anvils having offset heads, and in all sizes over ½ in. it is possible to gauge up to within 1/32 in. of a shoulder. A brass button is provided for marking sizes. This method of attaching the button is simple and can be

Fig. 1.—Built up gauge to test distance between plugs on indicator gauge.

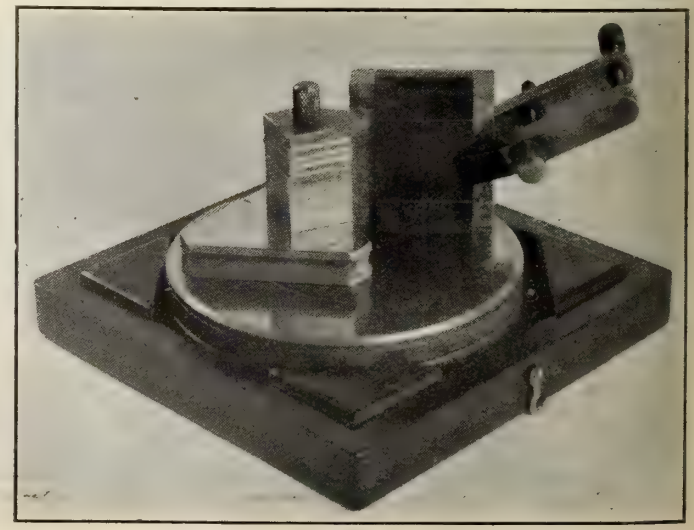

Fig 2.—Scribing layout for holes.

easily removed and the marking filed off, thus preparing for a new marking. Square anvils are also provided for this type of snap gauge, which in some lines of work possess additional advantages.

Plug Gauges

Cylindrical plug gauges are the universally accepted type of gauges used in gauging the diameter of holes. The long plug end is the low limit, and the shorter plug is the high limit end. The gauge pieces can be turned end for end thus giving longer life to the gauging parts. The fact that these gauging plugs, are reversible also makes them renewable. As the handles are standard and sizes marked on the gauging plugs, there is nothing to prevent various gauging pieces being mounted on these handles as may be required from time to time.

The cylindrical plugs are machine lapped by a special method which is a modification of the Hoke process, which, it is claimed, gives a finely finished surface entirely free from circular grooves, which result from grinding or hand lapping, and if present, cause in service rapid initial wear. The process produces gauges that are round and of uniform diameter from end to end. The measuring machine, fluid gauge, and amplifying gauge show no errors in this respect. These features in manufacturing together with the fact that a carefully selected alloy steel is used, assures an exceptionally long life to the gauges.

The "go" ends are held to a very small plus tolerance from the marked size, to allow for wear. The "no go" ends are held to a still smaller minus tolerance, as they are subjected to little wear and must accept work which is exactly up to the allowable limit. The blanks are all seasoned before being lapped. The seasoning process is done with the idea in mind of bringing the steel to a point of molecular rest, as when such a condition prevails expansion and contraction is uniform and at a given normal temperature the size will be always the same.

The handles are of hexagon stock, giving ample space for marking tool and operation numbers. The method of fastening the handles to the gauging plugs is rather novel. Three prongs on the handle, of 90 deg. included angle, engage three grooves of 75 deg. included angle, in the gauging plug. By means of a simple screw through the gauge, the wedge-like prongs are forced into the grooves. This provides a self centering tripod support free from "rock" or "shake" and very sensitive to the "feel." Thus practically the rigidity of a solid gauge is obtained. The screw end projects on the "no go" end and is flush or comes below on the "go" end which necessitates the gauge always being placed with the heavy end down. Handles are made in the single or double end design in all sizes.

The larger sizes of plug gauges are constructed somewhat differently than the smaller ones. Any standard plug

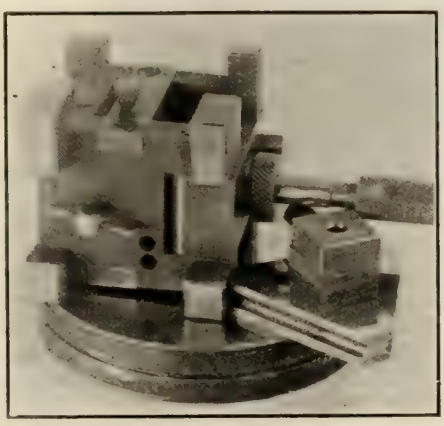

Fig. 4.—Checking a jig.

gauge over 2½ in. becomes a heavy gauge and in order to make the gauge lighter the construction of the "go" end is changed. This hollow construction applies to the "go" plug being lightened by a web-and flange construction. Two discs are forced into the ring on a taper before grinding and grip the central tube, holding the parts securely. The reversible feature provides double the usual wearing surface. Three prongs on the handle are forced into three grooves in the bushing, providing a three point self centering tripod support without "rock" or "shake." The washer at one end, and the handle at the other, bear on both the stay-tube and the discs, binding the assembled gauge-head to the handle. The "no go" ends have solid ends

Fig. 6.—Using a mikecheck for testing micrometers

of the web and-flange construction. The practical application of these gauges is very simple and has no obscure or outstanding features of interest.

Thread Gauges

The gauging of internal threads is a very delicate business as compared with gauging a plain hole with a plug gauge. The diameters of the thread, (root, pitch and outside) the lead of the thread, and form, all have to be gauged for accuracy. Thus the proposition has several variable quantities as opposed to only one, diameter, in the previous problem. Many thread gauges are reversible and renewable as is the cause in the plug gauge construction. The same special alloys are used and in many ways the method of manufacturing is similar. These gauges are interchangeable with the plug gauges on the standard handles, as the trilock method of locking to the handles is used.

The length of a thread gauge is not governed by any definite calculations, and is usually made up to the desire of the user. The finer the pitch the shorter the gauge required is, of course, an obvious conclusion. Reversible or renewable types of thread gauges were not popular in the past, as the methods used to secure them to the handle were far from being rigid. Thus new designs of locking, which do away with the objectionable "rock" and "shake" have done much to duplicate the sensitiveness of a solid gauge, and thus increase the usefulness of the modern reversible design.

Where the limits of the work are fairly large, extreme accuracy is not required in the gauges. "Working" gauges made to the tolerances recommended by the National Screw Thread Commission,

Fig. 3.—Checking a pro'le gauge.

Fig. 5.—Measur'ng a rack type gear cutter.

are manufactured in all forms and sizes. They have the same appearance and wearing qualities as master gauges. They are not lapped, but ground closely to size, perhaps .0005 in. being left to allow for wear.

A valuable feature first introduced in the reversible thread gauges is the ideal chip groove for carrying dirt, and chips, ahead of the guage when entering the hole. The usual form is that in which the blank is chamfered to the angle of the thread. The helix begins at the root diameter and builds up to a full cross-section of thread in one revolution. This form starts easily in the work, but the growing helix wedges any chips or dirt between the gauge and the work. Pilot brushes attached to the gauge have been used to avoid this trouble. Another expedient is the three chip grooves; here the thread reaches its full cross section in about 90 deg. and a chip is often wedged tightly before reaching the space provided and the groove fails to catch it.

A more efficient device is where the first convolution of the thread is removed. The sharp edge cleans the thread effectively, but the gauge is difficult to start and the edge soon becomes nicked. The ideal chip groove starts in its hole as easily as the first mentioned because it retains the growing helix except at a small portion. Just before the full thread is reached a small groove is provided that collects all chips and protects the thread from injury.

In the thread template gauges the locking screw is tightened so that the threads of the taper screw form a perfect dowel in both planes—something which has been lacking in many previous types of adjustable templets. The importance of accurate doweling to maintain a true helix is obvious. Both screws are readily sealed after setting. These gauges are made in all sizes from 1/16 in. to 5 in. or larger. The first thread of the templet is chamfered to the angle of the thread, for ease in starting. The ideal chip groove can be furnished, but is not usually required because a male thread is more readily cleaned than a tapped hole, and the slots in the templet provide chip space.

Gauge Blocks and Attachments

With a set of precision block gauges any dimension from .001 in. to over 10 in. can be obtained in increments of .001 in., while any dimension from .2000 in. to over 10 in. can be obtained in increments of .0001 in. When the desired size is more than .5 in. two or more stacks can be built up to identical dimensions, for checking against each other for use on several jobs simultaneously. The attachments consist of one pair of inside caliper jaws with a radius of .125 in., and one set of inside caliper jaws with a radius of .250 in., one pair of outside caliper jaws, scriber, centre point, base, knurled screws, headless screws, long flat head screws, short flat head screws, slotted nuts, and six assorted tie rods. Each of the blocks is made from square stock and when machined the common dimension of all blocks is .950 in. square. A hole is provided in each block and by means of the different screws provided various combinations of sizes as well as various types of gauges and tools can be assembled.

The inside and outside caliper jaws, scriber and centre point, are finished flat on one side to fit snugly and adhere to the blocks and gauges. The scriber is finished to a knife edge on both sides of the point. These edges permit of sharpening indefinitely, without affecting the accuracy. The centre point is ground to a 60 deg. angle with the point .100 in. from the finished flat surface. The base is finished .500 in. in thickness and is flat and parallel on both sides.

Practical Application

Fig. 1 shows a series of gauge blocks buit up to test the distance between two plugs on an indicating gauge. The knurled screws facilitate the assembling of the blocks and permit handling with a minimum change of temperature due to heat of the hands. Fig. 2 illustrates a simple, rapid and accurate way of scribing a layout for several holes. Work clamped to an angle iron is placed on a tool maker's flat. Precision gauges built up to the desired size are set up on the base, the scriber is "wrung" onto the top of the stack and the first line is drawn. Gauge blocks are added or removed from the stack to give other dimensions. The whole layout can be made in a short time with the positive knowledge that the lines will be drawn with much greater precision than is possible with rule and divider. Fig. 3 illustrates the use of gauge blocks with a sine square set up for testing the angle of a profile or contour gauge. The square has a knife edge and a very small error can be detected when carefully observed.

Fig. 4 shows the use of a plug gauge and gauge blocks testing the accuracy of a jig. Fig. 5 shows the blocks used to test the angle of the teeth on a rack type gear cutter. It will be noticed that the proper angle is obtained by placing gauge blocks under the end of the fixture to which the cutter has been bolted. The gear cutter teeth in question have straight sides at an included angle of 29 deg. between the sides of the teeth in a tooth space. When the fixture is tilted so that the pitch line is inclined at 14½ deg. to the vertical the surface gauge shown should indicate that the side of the tooth is parallel to the surface plate.

The height of blocks required is easily obtained, if the distance between the V slots in the holder is known. Supposing this distance is 10 in. Look up the sine of the angle 14½ deg. in the tables of trigonometrical functions. Multiply the number found, by ten and you will have expressed in inches the height of blocks required.

Mikechecks are designed to check micrometers for errors which occur in manufacture or from wear on screws and anvils, or in relapping and adjusting. Such errors exist to an appreciable degree in most micrometers. By the use of a set of mikechecks they may be checked, not merely at zero and even inches but also at intermediate points. The importance of having a check on the accuracy of a micrometer is shown in the illustration. This micrometer has seen several years of hard service and the screw is worn in places. The anvils have been lapped true and the nut adjusted to show correct at zero. It also shows correct at the 1 in. position. It might be assumed that it would be correct at intermediate points, but the .5 in. mikecheck shows an error of nearly .003 in. at the half-inch point. Some micrometer errors are unimportant if known; a set of mikechecks makes it possible readily to detect such errors and to allow for them in working to close limits.

In relapping the anvil and spindle it is not easy to bring the surfaces exactly square with the axis, nor to tell when they are square. An error here shows periodically as the screw is revolved. The .094 in., .100 in. and .106 in. mikechecks give readings at three points separated by approximately a quarter turn of screw. Since three points not in the same straight line determine a plane, the squareness of the surface is proven if the three readings check. If not, the direction of the error is shown. Mikechecks, made of the special alloy steel as Hoke precision gauges and produced by the same process of lapping and aging for permanence, are accurate to within .000025 in. Neatly and conveniently contained in a knurled screw-top steel case which justs fits the vest pocket, the set consists of six blocks .094 in., .100 in., .106 in., .300., .500 in., and 1.000 in.. The ..094 in.. and .106 in. together make the equivalent of a .200 in. block. They are .7 in. dia., and will wring together as firmly as Hoke precision gauges. There is also furnished a single 2.000 in. mikecheck in a separate steel case. A few of these long mikechecks, with one set of the smaller sizes, may be used to check micrometers up to 12 in., at each tenth-inch from .100 in. up, and a quarter turn each way from these points.

A RECORD CASTING

The largest iron casting ever made in Great Britain and one of the largest ever produced in any country was recently turned out in a British factory. It weighed about 110 tons and the mould was built in a 16 foot pit. Seven hours were occupied in melting the metal, and the casting was poured in just under five minutes. Three weeks were occupied in cooling the casting. Owing to its enormous size and weight the casting had to be delivered by road, six traction engines being used for hauling it.

Remarkable Locomotive Wreck Salvage

Engine and Six Loaded Cars Collide With Others on Trestle and Fall Into Lake—Locomotive Raised by Means of Scows and Hauled Ashore on Submerged Rails.

By ROY A. HUNTER

THE Vancouver Machinery Depot, Ltd., Vancouver, agents in B.C. for Climax Locomotive Co., carried out, some little time ago, a job for which it is hard to find a parallel. A 50-ton Climax geared locomotive, owned by The Rat Portage Lumber Co., at Harrison Lake, B. C., was taken charge of by its train of six loaded cars of logs by reason of the fact that the air line stop cock had been overlooked when switching—with the result that the locomotive started down a 6 per cent, grade with the six loaded cars unconnected to the air brake system. These naturally took charge as the locomotive's own braking effort could not hold the train. After going upwards of 2,000 yards, the train ran out onto a trestle, over the lake, and there met, head-on, two loaded cars of steel rails. The whole mix-up dropped over into 35 ft. of water, and the locomotive came to rest on the bottom of the lake, having two cars of steel underneath her, and six cars of logs on top.

Prospects for salvage were at once reviewed, and divers reported a bad smash-up, and great difficulty in raising the wreck on account of the loaded cars above and below. Salvage was, however, undertaken by the Vancouver Dredging & Salvage Co., who had a hard time getting their gear to the site: Harrison Lake is inland, and the derrick scows had to be navigated up the Fraser river from the coast, and then across dangerously shallow flood water to the lake. After 8 days the wreck was raised by the derrick scows and, partially submerged, was worked gradually towards shallow water (see Fig. 1), where a submerged track had been built out into the lake a considerable distance, to receive the wreck. This footing accomplished, the wreck was very soon on dry land, (as shown in Fig. 2.)

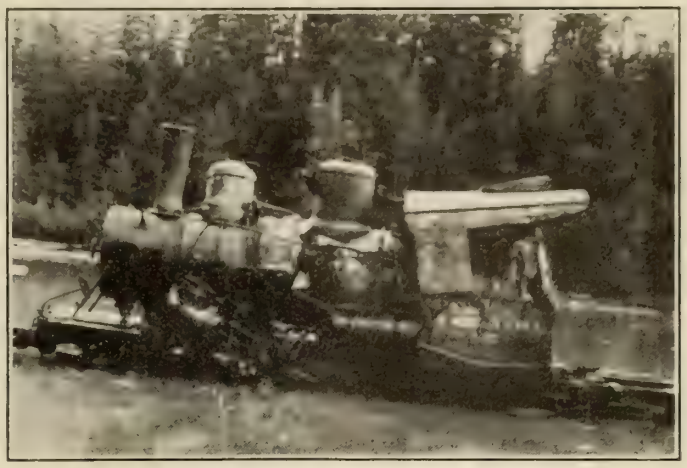

Fig. 1.—Locomotive in shallow water on submerged track.

The water having receded from the shallow flood connection to the Fraser river, it was found impossible to bring the wreck into the town for rebuilding. Accordingly "Mahomet had to go to the mountain" in the shape of the Vancouver Machinery Depot Ltd.'s rebuilding squad, armed with air tools, rivetting tackle and other necessary and suitable equipment. It was in the depth of winter and very cold, and the work was unavoidably outdoors. Every particle of the locomotive had to be dismantled and rebuilt from the ground up. Engine frames, trucks, boiler, and a few other main parts had escaped structural damage, but were full of the material and effects of Harrison lake mud, and required a large amount of very thorough cleaning and scraping and minute inspection; also other parts were irretrievably damaged or destroyed. New cab and fittings and controls were required; all shafts, etc., straightened and reset; tender and tanks rebuilt; all demountable gear stripped down, overhauled, and replaced; new air equipment was required and also new headlight equipment. The work of rebuilding was pressed on with all speed and was completed in 30 days from commencing the job—and this away from shop conveniences of all kinds and even reasonable warmth to work in. The locomotive was placed in commission again on completion and has since performed, in every way, exactly as brand new from the factory.

The Vancouver Machinery Depot, Ltd., who, by the way, do a great deal of the locomotive overhauling and rebuilding work in British Columbia, are to be congratulated on their major portion of the above most notable salvage.

Ten 4-page leaflets under one cover are being circulated by the Fitchburg Grinding Machine Co., Fitchburg, Mass., in which several models and sizes of cylindrical grinding machines are described and illustrated. In addition to a general description of each model, specifications are given. Both hand-operated and automatic types are described.

News From the Welding Field

Welders Wage War Against Flood

Repairing Gas Mains Over Night—Domestic Service Hardly Interrupted—Smelting Shutdown Averted—Two Well Known Firms Amalgamate

NEARLY every community has suffered interruption of its public utilities service at one time or another as a result of severe storms. Not very many years ago, if serious breaks occurred in gas mains, regardless of the cause, it was likely to occasion inconvenience to the public for a considerably longer period than is now required for making repairs and restoring service. The expedition with which havoc wrought by the elements can be remedied with modern repair equipment, such as modern welding outfits, for example, was instanced recently in California. The Gas Age (New York) describes the recovery and repair by oxy-acetylene welding of broken gas mains during one of the worst storms and floods experienced in the Pacific Southwest in a generation. The details are fairly typical of what public service corporations the country over are doing from time to time in similar emergencies, and are of special interest as showing the part gas welding and cutting are playing in service maintenance in the gas industry. After pointing out that a certain gas company in Southern California, operating 1,300 miles of transmission pipe lines that cross dozens of dangerous streams in serving five counties and 43 cities, had suffered a number of breaks in its lines during the storm noted, the writer proceeds:—

The first serious break in a company's main occurred when the San Gabriel river tore away the most of the El Monte bridge, then under construction, thereby severing the 4" high pressure transmission line supplying the city of El Monte. The bridge went out at five o'clock on the night of December 20th. The local superintendent of the company was notified at 6 p.m. In less than one half hour he had a construction crew on the job, had turned off the gas in the broken main and had begun the long battle in the river bed to recover the severed main.

The line across the San Gabriel, in addition to supplying the city of El Monte, is part of the Monrovia transmission system. The pressure at Monrovia dropped 50 pounds in less than one hour following the collapse of the bridge. The district superintendent and his construction force worked from 6 p.m. until the following morning at 3 a.m., when the break in the main had been repaired.

When the patrons of their company began their meals on the morning following the storm, they found their gas service as excellent as ever. The superintendent and a construction force had worked most of the night in a drenching rain, much of the time up to their waists in the river, in order to tie in the broken main. The welders had been on the job and had succeeded in welding the broken line, fastened it to the abutment still standing in the river bed, and finished the work in a raging storm.

The writer then recounts how other breaks were handled with such dispatch in other parts of the system that service was scarcely interrupted at all during the hours when required by consumers. It is an interesting commentary no less upon the energy of the present-day management of well-directed public utilities and their emergency crews than a revelation of what an industrial process that has been known only a little more than a decade has come to mean in the lives of the people to day. And after all, such emergency uses for oxy-acetlene are strictly negligible compared to its broad and growing applications in industry.

PROGRESS IN STEEL WELDING

In the early stages of welding steel and even up to recently, the practice consisted too often in filling a steel weld with whatever rod was ready at hand. This aften resulted in poor or weak welds and in a prejudice against the art in general.

Much research has been conducted recently both on the correct mixture of gases and the proper distribution to attain controllable temperatures as well as on the kind and composition of the rod which is to supply the welding metal. Attention has also been paid to the use of proper fluxes as well as to the needs in obtaining a high-grade weld of being certain that the base metal and the welding rod are fused at the proper temperature to insure a thorough mingling of the metals. It has been conclusively demonstrated, says Iron Age, that to obtain a weld as good or better than the original metal it is necessary to use a rod of a composition which will produce a joint better than the original or base metal. To attain this, rods of various compositions, including nickel steel, manganese steel and other alloys, have been developed. Their judicious use in the hands of experts is producing results hitherto unexpected.

It may safely be said that the art of welding has developed to a stage where, by controlling the temperatures, the materials and the fluxes, furnace conditions originally existing in the actual manufacture of the metal are imitated as nearly as possible at the welding point, to the decided improvement of the welded portions.

Large hydraulic car axle press before and after welding.

WELDERS AVERT CLOSING OF SMELTING PLANT

A job that is typical of the work being done by oxy acetylene welders and cutters at mines and smelters is illustrated in the accompanying illustration, which shows a 300-lb. hydraulic car axle press before and after being repaired. Figure 1 clearly indicates the seriousness of the fracture, showing the broken press in two pieces, while Figure 2 depicts the press after it was reclaimed by the welder. The latter view might easily be mistaken for a reproduction of an entirely new press, so well executed is the outer finish of the weld, and that its excellence is more than "skin deep" is attested by the satisfactory service the press is now giving under heavy working pressure.

The press shown is the property of a large refining company in the West. It is a small part of the company's great plant, but it was found to be very necessary to continued operation the moment it got out of "kilter," distinctly emphasizing its importance as a necessary unit in the machinery of production. There was occasion for congratulation, therefore, that the company maintained an oxy-acetylene department and had a welder capable of handling the repair without unnecessary delay. The weld measured from 3½ inches to 6 inches in depth and was about 6 feet 3 inches in length. The job was executed with one blowpipe and required about 200 lbs. of filling material. Oxweld equipment and materials were used.

WELDING FIRMS CONSOLIDATE

ANNOUNCEMENT has been made by the Air Reduction Sales that it has acquired all the assets, including the patents, trade marks and trade names of the Davis Bournonville Co., Jersey City, N. J., and Toronto. Negotiations effecting this move were consummated on March 17, 1922. It is understood that the purchase was accomplished without the need of public financing or bank loans. The consolidation brings together two large companies, whose histories have, to a great extent, been the history of the development of the oxy-acetylene welding and cutting industry.

In addition to its oxygen and acetylene producing facilities, Air Reduction owns a carbide plant, a welding and cutting equipment manufacturing plant, and extensive laboratories for the carrying on of useful research in connection with its various activities.

The merging of the Davis-Bournonville Co. with the Air Reduction Sales Co. brings to the latter organization all of the products that have been developed by "D-B." These products include hand welding and cutting torches in a variety of styles and sizes, suitable for all classes of service; machine torches for welding and cutting; pressure regulators; lead-burning torches; carbon-burning outfits for use on motor car cylinders; acetylene generators; tube-welding machines and tube-fabricating equipment; barrel-welding machines; weldographs for robe rails, milk cans, etc.; the radiagraph for straight line and circle cutting of steel plates and forgings; the oxygraph in two styles for cutting forgings, dies and shapes; the camograph for production cutting of hand-holes in steam-boiler headers, locomotive links and other parts made in quantity; the pyrograph for cutting boiler flanges to height and caulking angle in one operation.

It is the intention of the Air Reduction Sales Co. to continue the manufacture of "D-B" torches, acetylene generators, special machines, etc., under the supervision of the men who developed this famous brand of oxy-acetylene apparatus. The equipment will be marketed under the trade name of "Airco-Davis-Bournonville" through the medium of the Davis-Bournonville service organization in combination with the extensive service system that has been built up for the distribution of Airco oxygen, Airco acetylene, and other Airco products for welding and cutting.

WELDING HEAVY FRAME OF STONE CRUSHER

Aside from the high cost involved in the acquisition of new equipment or replacement of parts when the services of a machine are suspended on account of breaks in some portion, the delay subsequent on the manufacture and delivery often make it an expensive proposition, so that the possibility of adequate repairs, either of a temporary or permanent character is the chief consideration at the moment. In the repairing of heavy machinery that is subjected to excessive strains and stresses the question of repairs is frequently deemed unsatisfactory, as it is essential that the initial strength be maintained after repairing so as not to affect the efficiency.

As a striking example of the value of oxy-acetylene welding to those who employ machinery of any kind, the illustrations given below should prove of interest. It shows a section of a large rock crusher, the piece weighing approximately 3 tons, which was completely broken at both bearings, the area of fracture being approximately 9″ x 14″. on each bearing.

The cost of a new part being very high (in the neighborhood of $1,000.00), it was decided to have the broken parts welded, if practicable. Perfect alignment was absolutely necessary and when welded the section had to be absolutely as strong as new and flawless. The work was undertaken by the Carter Welding Co., of Toronto, four operations being employed for 12 hours, and 2,400 ft. of oxygen and 2,000 feet of acetylene were required to produce the heat necessary for making perfect welds. The necessary preheating was done with charcoal and a gas and air blow torch.

The cost of a new part being $1,000.00 and the cost of welding $100.00, a net saving of $900.00 was effected by the employment of the oxy-acetylene process.

Ruper G. Bruce of the Van Winkle Co., will return to Toronto this week after an extended trip to Great Britain and Europe.

Recent Developments in Mechanical World

Testing of Lubricants

Viscosity is a measure of resistance to shear, but it is no direct measure of the lubricating properties of an oil. Oils of the same viscosity may have widely different degrees of "oiliness," this being a property which cannot yet be defined or measured with any great degree of accuracy. The rapid decrease in viscosity with rising temperature is a factor which must be taken into account where oils are used at high temperatures; but here, again, the oiliness is at least as important as viscosity in determining the maintenance of the essential film. Solid lubricants, states Manchester Guardian Commercial, should be regarded primarily as "fillers" for the minute interstices which exist in even the most highly polished surfaces. Their principal advantage is in reducing static friction by thus improving the surfaces, but they also reduce the internal friction of oils, particularly if used in the colloidal state, and colloidal suspensions of graphite in water form a lubricant which eliminates explosion risks in air compressors, and feed-water contamination where steam engines are concerned.

Hardening Steel by Overstrain

The well-known effect of hardening metals produced by straining them beyond the elastic limit was revealed in an interesting way by an experiment conducted recently. The letters comprising the words "Adelaide University" were stamped on the polished side of a rectangular bar of mild steel with a punch. They were then completely filed off, so that all apparent trace of them was removed, and the side was highly polished. The bar was then put in the testing machine and stretched to beyond its elastic limit, when the letters appeared as raised marks, still retaining the original high polish which had become dulled over the rest of the surface. The reason is fairly obvious. Whilst all trace of the letters had been removed by filing, the metal underneath had been overstrained and hardened by the effect of the punch, and this hardened metal under the letters still remained. The result, according to a writer in the Commonwealth Engineer, was that as the bar was stretched in tension, this hardened metal did not flow with the rest of the metal in the bar, but remained standing out in hard raised surfaces showing the original imprint of the punch. A precisely similar effect takes place if the bar is subjected to compression beyond its elastic limit, instead of tension, only in this case the letters are hardened depressions in the surface instead of projection.

Shale Oil Being Developed

Wells are now being driven in Australia and Tasmania with the hope of striking oil in some of the shales. Gas has been obtained but oil has been slow to reveal itself, though the deposits are thought to be rich.

The discovery by the Samara University of the edible qualities of "awsan" leads to the belief that the famine of Russia can be greatly reduced. Awsan is a swamp root, containing 70 per cent. of starch, some fats and a good deal of albumen. The university has the sanguine hope that it will have a remarkable effect in minimizing famine.

* * * *

The schooner "Maud," which is now repairing and outfitting at Seattle, will again be driven northward early in the coming Spring in an effort to prove Amundsen's theory. This theory is that by taking advantage of the right current, a vessel frozen in the ice will drift across the Polar Sea in less than five years. He has tried twice without success, a propeller having been broken in the second venture. In the next effort to be made the ship will carry two airplanes which will be furnished with sleds.

Cobalt Magnet Steel

MILLING CUTTERS are in some classes of work far more economical to use than the ordinary machine roughing tools. They carry a number of cutting edges, the pitch of which is governed by the nature of the work, viz., roughing, a coarse pitch of tooth is required; for finishing, only a fine pitch. These work in quick succession on the same surface, and cover a width of some inches at once. The saving in time is consequently considerable, says Practical Engineer. Ordinary machine roughing tools, on the other hand, cut with one edge or point alone, and the width of the material worked is no greater than that of this cutting surface.

Clearing Sand From Deep Wells

TWO INTERESTING cases of the application of compressed air to the removal of sand plugs in deep wells is given in the Engineering News-Record. "One well, with an eight inch casing 145 feet deep (from which about 100,000 gal. of water was pumped daily), became clogged with sand to such an extent that it practically stopped the supply. A test developed fourteen feet of sand and small gravel. A three-fourths inch pipe to the sand was inserted and air forced to the bottom, the rising bubbles keeping the water disturbed and the sand in suspension, and it was thrown out very quickly and at little expense. In another case, the well was 236 feet deep with an eight inch casing, and the sand was beginning to shut off the supply and get into the pump. There was available only 150 ft. of one-half-inch pipe which was connected up with a compressor. The rising air created enough suction to lift the sand and the water was clear and running free of sand at the end of 25 minutes. While in the case here cited, the compressed air injected below the sand plug removed the obstruction very successfully, it should be noted the arrangement was not what is properly known as the air lift."

A Remarkable One-Tooth Gear

WHEN A GEARING is required to give a large difference between the speed of the driving and the driven wheel, what is called double reduction is adopted. That is to say, the reduction in speed is made in two stages. A British firm, however, has constructed a most ingenious gear in which a ratio of 63 to 1 is effected with a single reduction. The gear is of helical formation and it has been run for some time transmitting 10 horse power at 1,000 revolutions per minute without sign of distress of wear. The pinion has almost been found to work satisfactory as a driver, and the efficiency of the gear is stated to be equal to that of any ordinary double reduction gear. It is expected that this gear will be used for a large variety of applications, especially for the lighter drives in which it is desired mainly to transmit motion. The first pair of gears of this type will be deposited in the South Kensington Museum, London, to form part of a permanent collection of interesting mechanical devices.

Recently a patent was issued in Britain to cover the use of nickel wool, which has been activated for the hydrogenation of fats. The nickel wool is treated with nitric acid. The nickel salt then formed is converted into the oxide and this reduced in hydrogen. The activated wool is packed in the reaction chamber through which in counter current the oil and hydrogen pass. By washing it with hot oil to take away the nickel soaps the catalyst is regenerated. Finally the oil is removed by solvents and heating in hydrogen takes place.

Now is The Time to Invest In Machine Tools

Present Conditions Demand Greatest Efficiency if Profit is to be Made—Machine Tool Salesmen Can Help You Plan Cost Reductions—Make Your Improvements to Equipment Now.

IN THE ERA of strong competition now upon the business world, the best way to make profits is to get more and better production at lower costs. You can never attain that with obsolescent and antiquated machine tools. Conditions demand the greatest efficiency you can get from your factory—the use of the best and most modern tools! Right now, when you yourself are not hurried by an excessive demand, is the time to plan your own cost reductions.

The machine tool salesman is a missionary for better production methods. You can never tell which one may offer something that will save you thousands of dollars a year. It is never safe to pass him by. You may waste some time with him, says the Natural Machine Tool Builders' Association, but some day will come a golden hour that will more than repay you for all your trouble. Let the machine tool salesman help you plan your cost reductions—let him show you what the builders have for you today.

There never was a period when the machine tool builder studied his business so closely as he has the last two years. He has improved the quality and accuracy of his work, junked his own obsolete tools—and put his business where he knows he has his costs as low as they can go! The forehanded user can now get the benefit of all this study.

Only Two Policies

Studies of the business cycle show that for investors in permanent equipment, there are only two policies: the few invest carefully when business is slack and prices are low; the many invest hurriedly when business is rushing and prices are high. Those who invest in tools at a high first cost, when money commands boom rates of interest, must compete with the few who invested at the low price, when money brought only low rates. The stock market, the raw material market, the Federal Reserve Bank reports, all say that time is now!

When business swings sharply upward and the prices of labor and materials go with it, machine tools then cost more. A machine tool is a capital investment that stands ten or fifteen years. Such slow "turnover" produces the greatest returns if the investment was made when the user could get the best quality and when, because the builders' costs were lowest, the price was also low. These conditions prevail right now.

Place Orders Now

If you and other machine tool users wait to order additional equipment until you reach the capacity of your present facilities, the machine tool industry must wait until after all other industries are in full swing. Then the machine tool builders must outbid their own customers for high priced labor and materials. Machine tool orders placed now will not only take up slack in labor supply, but also increase consumer demand for general products, and avoid later strain on the labor market. Besides, the investment is made under the most favorable conditions.

Secretary of Commerce Hoover has urged the railroads to invest in equipment now, because the low level of prices makes the equipment a better investment for the long pull, and because current orders stimulate all business and bring us all that much nearer to normal. If that is logic for the railroads, it is logic for any manufacturer that intends to stay in business.

Before you swing into full capacity production again, doubtless there are improvements that should be made in your equipment. Isn't it really better to invest now when good materials and labor are plentiful and cheap, than it is to wait for higher prices, slower and more uncertain deliveries, and have to accept, possibly, more hurried and less perfect workmanship?

War racked or "war baby" tools offered now at low second hand prices may be a liability instead of an asset. They are already more or less obsolete because of important cost reducing improvements made since. In the rush of high pressure production, it may have been impossible for the manufacturer to maintain his usual standard. Before you buy such possible liabilities, find out what the builder has to offer you now in the way of real asset investments.

Much Better Product

Machine tools are a lot better than they were during the war, for many reasons. The current models are greater labor savers, greater cost reducers, than any the industry has ever previously built. The machine tool builders now offer something so much better than any previous product, that, in some cases, the user could not afford to accept the older types of machines as a gift.

When transportation is as cheap as it was in 1914; and wages are as low; and working hours as long; and taxes as moderate—then it may be possible for machine tool prices also to return to the 1914 level. But will the time ever come? Waiting for such a time before investing in equipment you really need, can only result in your sacrificing in production costs far more than the anticipated saving in price of the equipment. You pay more for the machine you do without than you pay for the one you buy.

Machine tool prices now quoted by builders are away down from the peak. These are for tools with the latest labor saving features—many of them perfected since the war. They are for tools that have been made unhurriedly, of the best materials, by the few finest machinists in the industry—the men who were kept on when the others were laid off. The wise user will make his investment now and avoid the rush that always booms prices in every period of prosperity.

THE TWENTY-FOURTH ANNUAL CONVENTION OF THE N. M. T. A.

The twenty-fourth annual convention of the National Metal Trades Association will take place at the Hotel Astor, New York, on April 19th and 20th. The program for the year, it is reported, is in many respects the most attractive which the association has ever been able to offer, subjects having been selected which it is felt everyone is vitally interested in at this time.

Among the subjects of vital importance to the metal trades which will be discussed at the convention is that of training apprentices to be the skilled all-round workmen. There are a great many methods of training apprentices in vogue in factories and shops to-day, and the committee on apprenticeship has examined these systems with great thoroughness. It has sought to incorporate their virtues and eliminate their defects in a training course which it has evolved. This course may be used in every type and size of plant.

A report which will be submitted at the convention will show courses of shop work for the apprentice, suggestions for a standard diploma, for an interchange of apprentices among the smaller or specialty shops, and other aspects of the apprentice situation which have occurred to only a few of the more advanced manufacturers.

Conditions in the coal mining industry and on the railroads will be discussed by speakers of national prominence; finance; the relation of the farmer to industry; the progress which the city of San Francisco and other large cities have made in emancipating themselves from labor union domination; future industrial conditions in the light of the European situation—these are only a few of the subjects which will also be dealt with by able speakers.

Practical Ideas for Shop Executives

TOOL HOLDERS

By Hubert Bentley, A.M.I., Mech. E.

A little careful attention paid to the tool equipment of the ordinary machine tool will generally result in increased output and reduction in costs, and often for a very trifling outlay. There is no doubt that the elaborate systems of toolholders to be found on the automatic capstan and hexagon turret lathes have helped tool designers considerably when the equipment of ordinary lathes has been under consideration.

An interesting planing machine toolholder is shown in Fig. 1. This was designed to provide the necessary relief for the tool when planing down a vertical face from one of the ordinary cross slide toolboxes. It is the usual practice for a toolbox to be pivoted or hinged so that on the return stroke of the table the tool may be lifted or relieved in order to prolong the life of the tool. This is quite satisfactory so far as horizontal planing is concerned but if vertical planing has to be performed from the same toolboxes it is ineffective. Side toolboxes of course surmount this difficulty, being hinged in a similar manner to the cross slide toolboxes. Where no side toolboxes are fitted to the machine, however, it is necessary to utilize the available toolboxes for vertical planing and the toolhandler shown in Fig. 1 is a very useful machine accessory.

The toolbar is of 2 ins. square section material and bolts to the cross-slide tool box by two bolts. A tapered hole in the lower end of the tool bar receives the toolholder itself. This is held securely in position by a hexagon nut and a square peg in the shank which fits a groove in the washer behind the hexagon nut prevents the nut from working loose when the thrust comes on the tool. The tool block holder is planed out to receive the steel tool block which swivels on a suitable bolt in a similar manner to the ordinary toolbox. The thrust due to cutting is effectively taken by the projecting lip shown in the detail at A. Three-eights square section tool steel is employed and this is gripped by two square head screws. In order to ensure the return of the block to its normal position after the idle or return stroke has been made, a flat steel spring is fitted behind the block.

In Fig. 2, a slotting machine toolholder constructed on the same principle is shown. In many slotting machines, no provision is made for relieving the tool on its upward stroke so that the tools require frequent grinding as the cutting edge is quickly worn away, hence the introduction of the example described. The tool bar is of similar section to the one just described and secured by two bolts to the tee slotted ram end. The bar is grooved at the bottom for receiving the steel tool block which is pivoted on a suitable bolt. On the return or upward stroke the toolblock swivels on this bolt and the cutting tool rides on the work. When slotting, the toolblock lip takes the thrust and a flat steel spring returns the block to its normal position after being relieved. In this case ½-in. square tool steel is employed and held in place by a steel pad and grub screw. This arrangement takes up considerably less room than when projecting head screws are employed.

The application of toolholders of this character while increasing very considerably the productivity of a machine also results in a considerable saving in tool steel, due to the longer life given to the cutting edge and to the small pieces of tool steel employed.

CARE REQUIRED IN MOUNTING GRINDING WHEELS

The mounting and maintenance of grinding wheels demands the exercise of special skill and observation. The wheels should be carefully examined before mounting with a view to detecting any damage that may have occurred in transit, storage or otherwise. Except in the case of very small sizes, all wheels should be lightly tapped with a hammer before mounting and should not be used if they fail to ring clear. In applying this test, care should be taken to remove all sawdust and extraneous matter from the wheel. Grinding wheels must never be forced into position on their arbors or spindles. They should slide on easily, but not too loosely. If the clamping nuts are over-tightened, the resulting strain is apt to crack the wheel. Care should be taken to tighten only enough to hold the wheel firmly. Grinding wheels should under no circumstances be used without flanges. The flanges, which may be straight or tapered, should be inspected frequently, and when found out of truth should be straightened or replaced by new ones. Washers of rubber, leather or blotting paper, slightly larger than the diameter of the flanges, should be interposed between the wheel and the flanges.

HARDENING HIGH-SPEED STEEL

Hardening high-speed steel is usually carried out in a gas or electric furnace and the steel quenched in oil, free from water, until the oil ceases to flash on the surface of the piece. Pieces with fine cutting edges are advantageously brought to a quenching temperature by immersing in white-hot lead, after the necessary preliminary heating to a color, or in a bath of barium chloride kept at a proper temperature (from 2275° to 2325° F.) by means of a pyrometer. A little potassium ferro-cyanide added to the bath will prevent decarburisation of cutting edges while heating. Tools should be ground with light pressure on a wet stone to avoid cracks due to sudden expansion of the surface caused by the heat of grinding. The high heats necessary for the successful hardening of high-speed steel have a tendency to deteriorate slightly the outer portion of the metal, and consequently it is advisable that the deteriorated metal should be ground off after hardening and before use. At least 1/32 in. should be ground off the tool and front of the nose of the tool. Grinding should be done on a free-cutting emery wheel under a copious, steady flow of water. An intermittent flow of water, allowing the tool to heat up, after which it would again come into contact with water, would cause surface cracks.

Mill scale and adverse weather conditions promote corrosion of steel. Mill scale and all rust must be removed before any paint is designed to protect the clean steel surface. The second coat of paint protects the first coat from the weather and this second coat must, therefore, be impervious to moisture and frost.

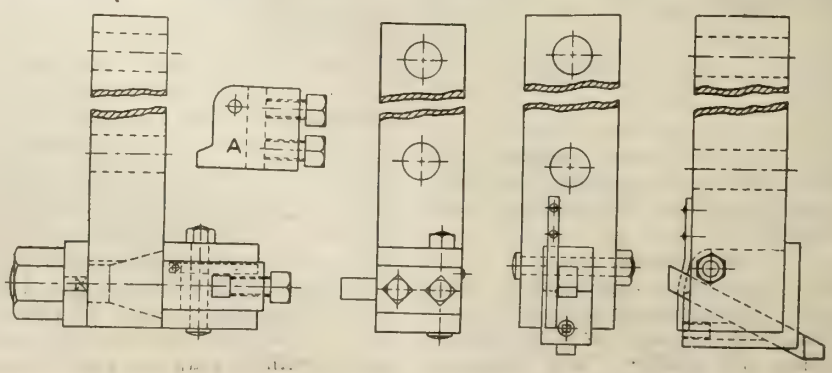

Fig. 1.—Left, relief tool holder for vertical planing. Fig. 2.—Right, relief tool holder for slotting machine

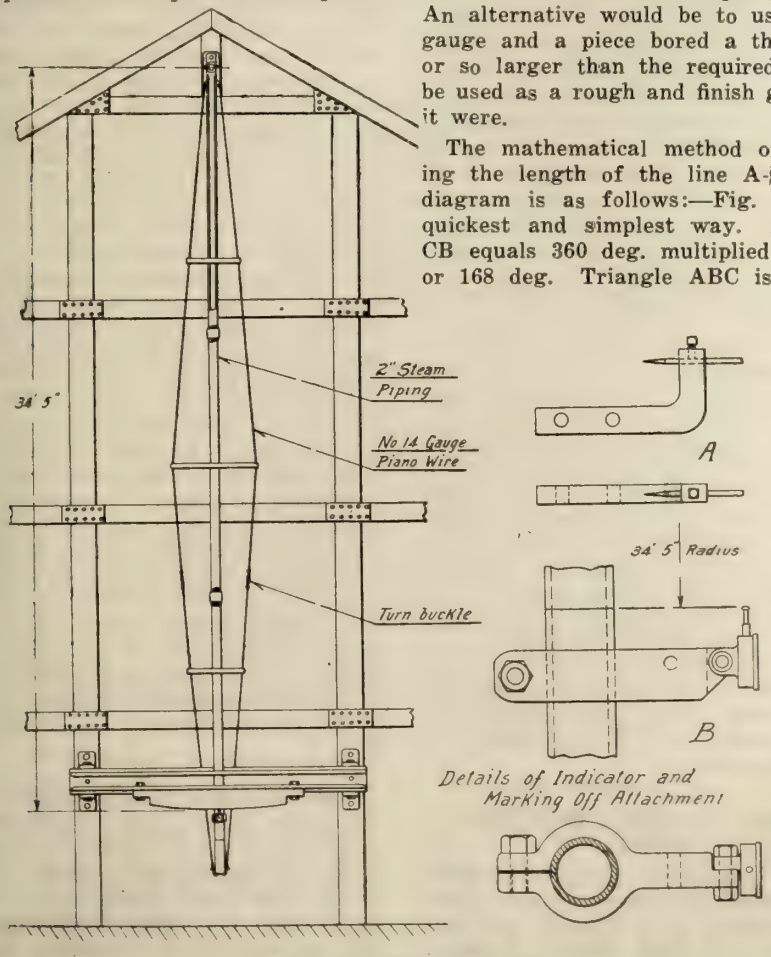
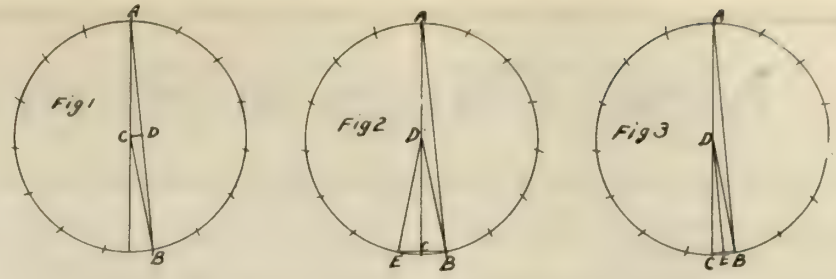


CAMBERED ROLLS

By R. Harrison



In the production of sheet metal, the chilled iron rolls used in the mills are often supplied with cambered surfaces. This curved or cambered surface is reproduced on the roll body from a camber bar of known curvature fitted to the reciprocating table of the grinding machine on which the roll is ground.

Contact between the camber bar and the wheel head operating mechanism is made through a hardened steel roller, which in turn operates through a series of levers, ultimately imparting the very slight reciprocating motion to the wheel head necessary for the reproduction of the camber. When it is realized that the actual camber on the roll is only a matter of perhaps a few thousandths of an inch, on a roll say thirty inches diameter by forty-eight inches long, it will be readily credited that the generating mechanism to produce it must be both extremely accurate to start with and durable in use. Although all components are important, the camber bar from which the form is generated being the basis, it must necessarily be made to very close limits of accuracy. Several methods are available by which the correct radius on the camber bar can be struck, but the scheme illustrated herewith being the simplest and most direct, the results are naturally more accurate, and what is more important, less costly to attain.

Suspended from a point in the apex of one of the bays under the pitched roof of the erecting shop is a length of 2 inch steam piping, while braced to eliminate side whip with a couple of piano wire struts tensioned by suitable turnbuckles. Varying lengths of radii can be obtained by swinging the pipe from pivotal holes drilled at pre-determined distances. A line to machine is struck across the length of the camber bar by traversing by hand the tool point shown in detail at "A." After profile milling, the bar is again mounted on the wall brackets and checked over by means of a dial indicator mounted as shown at "B." Final correction is obtained by draw filing.

Device for testing camber bars.

Diagrams showing solution of reamer query.

SIZE OF REAMER QUERY

By H. T. Osborn

Reply to query by D. J. as to gauging a reamer having an odd number of teeth, the following solution is submitted. The calculations here given are on the basis that all flutes are equally spaced. An alternative would be to use a ring gauge and a piece bored a thousandth or so larger than the required size, to be used as a rough and finish gauge, as it were.

The mathematical method of obtaining the length of the line A-B in the diagram is as follows:—Fig. 1 is the quickest and simplest way. Angle A CB equals 360 deg. multiplied by 7/15 or 168 deg. Triangle ABC is bisected by radial line CD, thus forming two right triangles.

As ACD equals one-half of 168 deg. or 84 deg. and AC is 1 in. (the radius of the reamer), length AD equals sine of ACD x AC, or .99452 in. AB equals .99452 x 2 equals 1.98904 in.

Fig. 2 gives the same result, thus:—Angle EDB = 360 ÷ 15 = 24 deg. CDB = 24 ÷ 2 = 12 deg. DC equals cos. CDB × DB = .97815.

AD + DC = 1.97815 in. = AC. CB = DB × sine CDB = .20791 in. Having the length of AC and CB, AB can be found by

$\sqrt{AC^2 + CB^2} = \sqrt{3.9563} = 1.9891$ in.

Fig. 3 is based on the principle, that if two straight lines are drawn from the extremities of a semi-circle and meet at any point on the circumference they will form a right angle. Thus, ABC is a right angle. AC being known, CB is found by bisecting at E, forming right triangles as shown. Either one is solved to find CE or EB.

CLEANING OILY MACHINE PARTS

One of the most troublesome of the minor problems in the repair and overhauling of motor cars and other machinery is the perfect cleaning of parts which have been thoroughly soaked in oil. This problem is very ingeniously handled in the new central repair works in connection with London's great motor omnibus service. The parts to be cleaned are placed on wire trays mounted on a conveyor which moves very slowly through a cylindrical casing inside which are mounted on a number of pipes perforated with holes ⅛ of an inch in diameter. Hot caustic solution is forced through the pipes by a pump, and the multitude of jets reach every part of the gear wheels and other portions of machinery passing through. When the parts emerge from the cylinder they are practically free from oil. In this way a process which generally is most prolonged and laborious is perfectly carried out in a minute or two.

WATER WHEEL CORROSION

In the water wheel work the blades of the wheels travel at very high speeds. The combined effect of the evacuation resulting from this high speed and the corrosive action caused pitting in bronze, this pitting being sufficiently deep to bring about failure. Monel metal replacing such bronze has shown more than 9 years' service without a sign of pitting.

New Things in Shop Equipment

CONSOLIDATED TAP AND TOOL HOLDER

A very useful tap and tool holder has recently been placed on the market. The chuck is constructed along the lines of a drill chuck. It has a rather wide range, the maximum capacity is for taps up to ⅝ in. in dia., and other tools in proportion. The jaws are provided with V grooves extending parallel to the axis of the holder. These jaws are serrated throughout their whole length, in order to provide a secure grip. The opening of the jaws may be easily adjusted by turning the sleeve, which is knurled and has a maximum di. of 1⅜ in. The length of the handle is 7½ in. and the length of the tool itself is 4 in. The tool is manufactured by the Consolidated Tool Works of New York City.

PRECISION ANGLE AND MEASURING IRONS

There has been recently placed on the market a precision angle iron built in three sizes. The device is made of cast iron and is intended for holding work on a machine table. Two slots are provided for clamping one leg to the table, while the slot in the other leg can be used to secure work to the angle iron. Two ribs brace the legs to keep the device from distorting. The iron is made in the following sizes: 4 x 5 x 5 in., 6 x 6 x 8 in. and 8 x 10 x 12 in.

The same firm also is marketing a precision measuring iron. The device is especially intended for use in setting and aligning work for accurate boring operations. It is provided with a bolt hole and keyway, so that it can be easily secured to the table of the machine. If it is so desired it can be used for clamping work that is to be machined. This tool is made in two sizes: 2½ x 6 x 12 in. and 4 x 8 x 21 in. These tools are manufactured by the Simplex Tool Co., of Woonsocket, R. I.

BENCH GRINDER WITH SELF-CONTAINED EXHAUST FAN

There has recently appeared on the market, a bench grinder, which has as a component part, fan provision for removing the dust caused by grinding. Outside the bearings are located centrifugal fans which blow the dust directly back through the exhaust pipe connected at the rear of the grinder. A separate fan and motor are not required. This design is best adapted for use in the case of single machines where it is possible to conduct the dust directly outside. In a measure, it does not attempt to replace large and powerful exhaust systems as the fan has not capacity to convey the dust through a long pipe, particularly if many bends are encountered. The self contained motor is of the induction type, fully enclosed, designed, for single, two, or three phase alternating current, and built in half and three-quarter h. p. sizes. Hess-Bright ball bearings, fully enclosed, are used. The fans and the two grinding wheels, are located outside the bearings. The grinding wheels are well guarded. Adjustable tool rests are provided for both ends of the machine. The grinder is made by the Forbes and Myers Co., of Worcester, Mass.

LARGE PLANER

A large planer that has a distance of 15 ft. 2 in., between the uprights and can take work under the cross rail that has a height of 10 ft. 2 in., and has a table 38 ft. long by 12 ft. wide, has recently been built for specially large work. The machine is driven by a 75 h.p. motor of the planer reversing type. A large range of cutting and return speeds, which can be instantly changed, are provided. The planer is also provided with a device for "air" or spot planing. This device automatically increases the speed of the table on its cutting stroke when a long stretch of air is to be cut, and automatically slows down the table just previous to the entry of the tool into metal. The return speed remains constant. Five tool heads are provided. Two heads are carried on the cross rail, one extension-slide side head on each upright, and one head on a separate column. The independent feed and power rapid transverse in all directions for the two cross-rail heads, and the two extension-slide side heads, are so arranged that each can be engaged for power rapid traverse in any direction, at the same time the other head, or heads, are feeding. A 15 h. p. motor located at the top of the girt, furnishes power for raising and lowering the cross-rail and for the power rapid traverse to the heads. Automatic tool lifters are provided for the cross rail heads. Forced lubrication of the table ways, as well as of the driving gears, rack and shaft bearings, is furnished by means of pumps and an oil filter system. A separate tool head, or column, fastened to the bed some distance ahead of the right hand upright, carries a saddle which is provided with vertical feed and power rapid traverse in both directions. This power is furnished by a separate electric feed motor. The planer was manufactured by the Betts Machine Co., of Rochester, N. Y.

SMALL PORTABLE ELECTRIC DRILL

A very small and compact portable electric drill has recently been placed on the market. It is intended for general work of a light nature. It has a capacity that will permit it to drive with ease a one quarter inch drill. It is equipped with a Universal, high-speed motor, which will operate on either direct or alternating current, and in the case of alternating current it will operate on either direct or alternating current, and in the case of alternating current it will operate on anything from 25 to 60 cycles. The housing of the motor is made of aluminum and is finished in black. The diameter of the motor is 3 in. All shafts are ground to size and the gears are made of heat-treated tool steel and all gears have helical teeth. The spindle carries a No. 1 Jacobs chuck. A ball bearing takes the end thrust of the drill spindle. Ten feet of cord is furnished as regular equipment, as well as the plug and switch. The drill is ten inches in length, overall, and weighs four pounds. The drill was designed by Joseph W. Jones and is manufacteured by the Consolidated Instrument Co., of America, New York City.

HIGH SPEED METAL CUTTING HACK SAW

There has recently been placed on the market a small hack saw that is designed to use very thin blades and to operate at a very high speed. The number of strokes per minute ranges from 60 to 100, the length of the strokes being 6 in. Twenty-one gauge blades from 10 to 12 in. long are used. It is claimed that the high speed is made possible by the positive mechanical lift on the non-cutting stroke. This action gives clearance to the teeth on the back stroke which prevents dulling from the dragging action. The cut is taken on the draw stroke, and gravity pressure only is applied to the saw blades. An automatic knock-out is provided to stop the saw when the cut is completed. It is stated that the saw is very economical in blades, time, and material. The saw frame guide holds itself at any height, automatically. The saw frame slides on V ways which are provided with adjustments for wear. The normal capacity of the machine is 4x4 in., but an adjustment is provided whereby it can be increased to 6 x 6 in. for large work. The height to the top of the table from the floor, is twenty inches. The floor space required is 38 in. by 12 in. The weight of the machine is 150 pounds. The machine is manufactured by the Racine Tool and Machine Co. of Racine, Wis.

PORTABLE WINCH HOIST

A rather novel type of portable winch hoist, which is very useful in machine shops, has recently been placed on the market. The frame of the hoist is similar to that of a large "horse," having four legs, each pair converging at the

top and supporting a central beam. Steel angles, well braced and riveted, are used to provide a rigid unit. The feet are provided with large castors. When not in use the two pairs of legs are arranged so that they can be folded together and the hoist left up against a wall, where it would occupy but little floor space. The interesting feature of the hoist is the arrangement of the lifting chains. Two chains are provided, which can be operated independently. The chains are mounted on drums which are carried on the horizontal hexagon shaft supported by the top beam. These drums may be easily slid along the hexagon shaft to any position desired. The shaft operating the drums is revolved by means of a crank, which, through the medium of a chain and sprockets, applies power to the final drive of a train of gears mounted on the top of one end of the frame. Owing to the fact that one end of each chain can be uncoupled, two speed ratios are provided. The leverage with the direct lift is 200 to 1 and with the double lift, the leverage is 400 to 1. A pawl engages the teeth of one of the large gears, so that the load may be held in any position desired. This pawl provides points separated by 1-16 of an inch at which the load can be held. A friction brake is supplied for lowering the load. This brake acts on the chain pinion shaft, where the advantage of the purchase, is made use of to assist the braking operation. Two sizes of hoist are made. The smaller has a capacity of 4,000 pounds, has a width inside the legs of 8 ft. and a height of 7 ft. 9 in. The weight of the hoist is about 450 pounds. This smaller hoist can be furnished to special order with a height of 9 ft. Two sling chains are regularly furnished with each hoist. The larger size has a capacity of 8,000 pounds. In this hoist the lifting chains are carried on trolleys which automatically position themselves over the centre of the load. The chain is wound on a winch at one end of the frame. Two speeds are also provided. The rapid speed is gear driven, and the other is actuated through worm gears for the lifting of heavy loads. Either method may be engaged without the use of wrenches. The brake and locking device are very rugged. The hoist has a width of 9 ft. between the legs, a height of 9 ft., and weighs 1,000 pounds. These hoists are made by the Manley Manufacturing Co., of York, Pa.

PORTABLE WOOD-WORKING MACHINE

A machine has recently been placed on the market, which is portable and designed for general wood-working use. The mechanism is mounted on a bench or stand, which can be easily moved about. It carries an 8 in. cross cut saw and an 8-in. rip saw, a jointer, boring and mortising attachments, a miter board and other attachments. A motor of one-half h. p. operates the machine. Current can be supplied from an ordinary light socket. The motor is mounted on a slide that can be swiveled so as to bring the pulley into proper position for driving that part of the machine that it is desired to operate. When connected to the cross cut saw it swings and slides with it. Hardwood up to 2 in. in thickness can be handled by the machine. In the pattern room it is especially useful for grooving out core boxes, for cutting accurate joints for segment work, for small planing and ripping and making mitres at any angle. The advantage is that a great many jobs can be done on the spot at a greatly increased rate of speed over the hand method. At the same time it saves time, and is more economical, than the method of taking the work to a large stationary machine, and tying up that machine from time to time. When the cross cut saw is used, the motion is straight and not in an arc as with a swing saw. The mitre box can be set at any angle, and the dadoing machine is in full view of the operator. The saw runs at a speed of 4,200 r. p. m. and the jointer at a speed of 4,800 r. p. m. Both the rip saw and the jointer operate at the same time, so that two men can work simultaneously. The table tilts for ripping bevels. The machine requires a bench space of 18 x 24 in. The weight of the machine is about 240 pounds. The machine is manufactured by the Hutchinson Manufacturing Co. of Norristown, Pa.

ARMATURE PRESS

An armature press that is intended for the use of electrical repair men has recently been placed on the market. The construction and capacity of the press enable it to be employed for assembling operations such as putting in place piston rings, spindle bushings, gears and similar work. The frame is of cast steel and is capable of withstanding a pressure of 3,000 pounds. It is 17 in. in height overall, and an opening provided in the base is 5 in. in dia. A hardened steel plate, made in two pieces, having three different sizes of openings is furnished to accommodate small work. The plate is held together by two bolts. The two halves can be slipped under the bearings of an armature shaft so that the shaft can be pressed out of the bearing. The working height between the plate and the bottom end of the arbor, in the raised position, is 9¾ in. The press is manufactured by the Napier Machine Co., Inc., of Napier, Ill.

STRIP METAL FILING MACHINE

A machine has recently been built for the purpose of filing the edges of strip metal. It will be of special use in cold rolling mills, where metal is rolled wider than necessary, then cut in narrow strips and wound in coils. Such strips of metal are used to make springs, hack saw blades, and similar articles, and before such articles are made it is desirable to remove the sharp edges. Thus different classes of work call for edges of different kinds such as round, oval, bevelled, or special shape. The coil of metal to be filed is placed on a spool on the spindle. The end of the strip is passed between the two clamps at each end of the table, and then gripped and wound on a power driven spool that draws the metal strip through the machine. The design of the machine is such that power must be applied by a unit seperate from the filing machine. The machine is equipped with fifteen pairs of semi circular heads carrying the files. Each head is mounted on two rods placed one above the other and transversely with the centre line of the machine. The rear head of each pair is secured to the rods by set screws, while the front head is a sliding fit and is held in place by the tension of a spring. Each of the heads carries a file holder, in which is mounted a file 1¼ in. wide by 2¼ in. long by ¼ in. thick. The positions of the files are adjustable by swinging them around on the semi-circular heads and locking them in position. An adjustment of 180 deg. is provided, and it is possible to so group the files as to give the desired shape on the edges of the work. As the files operate in pairs, the pressure of a file on the work is counterbalanced by the pressure of the file on the opposite side. All the heads which are at the front of the machine, can be operated by a lever which pulls them forward, thus opening the filing space. In this way the inserting of a new coil of strip metal is simple. The metal passes in a straight line from one end of the machine to another. Strip metal of any gauge, and up to 3 in. in width, can be handled. The machine itself is rather simple but is very sturdy. It is capable of quick adjustment, and weighs about 1000 lbs. The machine is manufactured by the Duston & Clark Engineering Co. of Cleveland, Ohio. This firm are the successors to the D. & C. Engineering Co. of the same city.

MOTOR DRIVEN BENCH LATHE

There has recently been placed on the market a small bench lathe, which carries its countershaft mounted on an upright steel bar, which bar is supported from the headstock of the machine. The motor which drives the lathe is carried in a bracket at the back of the headstock. The swing over the bed is 10 in. and the distance between the centres is 24 in. The spindle is provided with a ⅝ in. hole throughout its entire length. The carriage is gibbed to the bed and is traversed by a screw. Instead of an apron, a bracket is carried down from the carriage, in which a nut is located. This nut engages the carriage-travel screw in the front of the bed. At the right hand end of the machine a crank handle is fitted to the screw. Thus all feeds are operated by hand. There are no back gears only the open belt drive is used. The motor is supplied with current from an ordinary lamp socket. The equipment includes motor, cord, plug, face-plate centres, centre rest and wrenches. Thus the lathe comes complete and ready to run. The manufacturers are the A. V. Carroll Machine Tool C. of Norwood, Cincinnati, Ohio.

Engage Only The Best

DURING the joint safety convention held in Toronto recently, the question of proper medical attention for injured employees was freely discussed. Several prominent industrial doctors including Dr. Starr, professor of surgery, University of Toronto; Dr. Baker, of the Massey Harris Co.; Dr. Scarlet, of the International Harvester Co.; Dr. Addison, of the Wm. Davies Co.; Dr. Gaby, Dr. Doolin and others, expressed their views on this most important subject, and without exception, they emphasized that cheap, inefficient doctors were a menace to industry.

Selfish motives did not prompt this unanimous opinion, for these are well up in their profession, have a splendid reputation, and do not require to use conventions as a plea ground for higher salaries. They were speaking from experience, and any one of these physicians could, if requested, tell of permanent disabilities caused through careless and inefficient medical treatment.

When a worker is injured, he deserves the best attention possible. Only doctors with a reputation should be engaged, and where a surgical operation is necessary, the best surgeon obtainable is none too good. How many plant managers would allow the doctor attending their injured workmen, to handle their case were they suddenly injured? Ask yourself this question, then if you do not consider the doctor handling your compensation cases good enough to look after you, it is time to change to a more capable physician.

During the discussion, Dr. Starr, who has had very wide experience during the war on surgical work of all kinds, brought out a splendid point. He suggested that some arrangement should be made whereby a specialist could be available as consultive head. That is, if a serious accident occurred, this man could look the injured workman over, diagnose the case, then instruct some other doctor what to do. As Dr. Starr said, "A man such as I have in mind would command a high salary, but the saving of life and money which would result, would soon offset the cost. Not only would it help the employee, but the employer as well, because, through careful treatment, the injured workman would be able to get back on the job all the quicker."

This is an important point for there is nothing lowers the morale of a worker quicker than long convalescence. Even if you cannot place an employee back on his regular task at once, start him on some lighter work which will take up his attention until he is able to return to his former duties.

During the war, Dr. Starr discovered that several soldiers could not use their hand owing to a shattered tendon. He performed an operation unthought of before, took a tendon from the arm where it was not called upon to function much and placed it where it would do the most good. The result was that the soldier was able to use his hand, and get back to the lines. A surgeon less capable would have hesitated to perform such an uncommon operation, which simply proves the need of selecting only the best doctors and surgeons to look after our injured employees.

Phenomenal Development of Repairs

THE DEVELOPMENT which has taken place in wireless telephony during the past few years is nothing short of marvellous. From an experimental stage the art has developed by leaps and bounds, until today even boys and girls from 15 years and upwards are able to receive messages intelligently.

Its popularity is almost beyond belief, and now that Canadian newspapers are taking up the task of distributing concerts and general news service, we can expect a wave of enthusiasm to spread from coast to coast.

A notable farm journal in Western Canada has announced the installation of a powerful radiophone broadcasting apparatus, and has promised its readers within a radius of 1,000 miles that they will be supplied with the latest world's news, concerts by artists of international reputation, etc, all by simply installing a receiving set at a small outlay.

Very little technical knowledge is required to operate such a set, and for the price of a good gramaphone, a home can be connected up to listen in on the different messages passing through the air, provided of course, the instrument is tuned up to the proper wave length.

But what of the future? Will the art of radio telephony develop to such an extent that every home will be equipped to listen in? If so, what type of instruments will be used? Will some standard method of transmitting messages be adopted, or will the arrangements be hap-hazard, every broadcasting station working independently.

It seems to us, before long, a standard type of instrument will be developed, more powerful than the cheaper style now in use, and that it will be leased at so much per month, just the same as we lease our telephones at present. Broadcasting stations will work to a standard plan, and perhaps pay certain theatres for the privilege of sending broadcast their performances. "Why should great singers to whom we pay fabulous salaries, sing for nothing to the general public?" may be the cry of the theatre manager of the future, so that we may soon reach the period where programmes are arranged in a manner somewhat like the large phonograph companies follow out.

Whatever transpires, we are sure of one thing, that radiophones will be of higher quality than used at present, and be almost in universal use. Every newspaper and trade journal of importance will have at least a receiving set, and until the last form is fastened to the bed of the press, readers will be supplied with the very latest news.

Strength Developing in Iron and Steel Market

Orders Well Distributed But Small in Volume—Bars, Plates and Shapes Stiffen—Likely to Advance—Machine Tool Sales Quiet With Small Supply Demand Fairly Steady.

DEALERS ARE NOW BUYING FOR STOCK

PRACTICALLY no change has taken place on Canadian markets during the week. The iron and steel section remains strongest of all, and there is quite a bit of talk to the effect that a slight advance will take place within the next ten days. At present, bars are selling at $2.75, but $2.90 may be the new figure. Some time ago, an increase was made in the United States, but so far Canadian dealers have not moved up in sympathy, competition being so keen, that they were afraid, and preferred to work on a closer margin.

Non-ferrous metals are weak, but scrap metals show signs of strength, although prices remain unchanged in both lines. Pig iron is decidedly stronger, and several users are coming into the market, asking for speedy delivery. It is known that the material ordered is not for immediate use, but fear is expressed by some that non-union miners may go out, thus tying up the pig iron business. Prices are firm, and shading is practically non-existent. Montreal reports that Buffalo producers have withdrawn all quotations.

Machine tools are in fair demand, and the same holds firm for small tools and supplies. Oils, greases, waste, and other miscellaneous lines remain in fairly active demand, prices in all cases being the same.

The coal strike is beginning to make itself felt in the United States, especially in the iron and steel industry. The striking in non-union fields is responsible for the trouble, and several firms have had to bank or blow out a few furnaces. However the situation is not serious, and after the Easter holidays the non-union men are expected back to some extent at least. The United Mine Workers are said to have no funds to speak of, so that severe opposition is not anticipated.

Pig iron demand in the States improves, and several users are sending in contracts to the mill with the price space left blank. No market is quotable, but prices are around $21 for bessemer, $20 for basic, and $21 for foundry. This is $1.50, $2, and $2 advance respectively, over the market two weeks ago.

Wire mills, which so far have stayed out of the wire nail and staple advance, have entered the fold, and quote similar advances. This makes everybody quoting on the same level. Bars and small structural shapes are up $2.50 a ton, but on attractive orders, prices have not advanced quite so much. Business generally is improved.

Toronto

April 19, 1922

WHILE no decided improvement can be reported in any branch of the local market, there is a much better tone in the trade. Dealers feel more confident, and are beginning to realize that the process of improvement is going to be a gradual one. Some were unfortunately looking for big things in April, but the movement so far this month has shown them conclusively, that they were over optimistic.

Iron and Steel—The strongest movement is in iron and steel, although the business being closed is purely seasonal. A few good sized contracts in street car track material, etc., have been secured, but this has not occurred during the week, it being a gradual development which is being closed as the work proceeds. In the general market, orders are for small amounts, but the total is not discouraging under the circumstances. The recent wet weather has hindered operations to some extent, and the Easter holidays coming in have also spoiled the week's business.

There is no feature, all lines being in fair demand. Boiler tubes are down a little in price, the changes being shown in the list below. These prices represent about a 10 per cent. drop. Recently business has been so poor in tubes and competition so keen, that nine out of ten firms here were quoting the present listed prices, sometimes as they thought, on the quiet. However, the figures now quoted represent the low level.

There is still considerable talk of an advance in the price of bar and shape material, and the consensus of opinion seems that it will occur either this week or the next. Competition remains so keen however, that everyone seems to be afraid to make the first move, although the spread is not so great locally, as it is in the States. If dealers get their way, the price will go up to $2.90 in place of $2.75. Following are present prices on iron and steel bars, also pipe:

Iron bars	2 75
Steel bars	2 75
Reinforcing bars	2 75
Steel hoops	3 75
Tire steel	3 00
Spring steel	6 00
Band steel, No. 10 gauge and 3-16 in. base	3 25
Small shapes	3 00

BOILER TUBES—	Seamless	Lapweld.
1 inch	$21 00	$.....
1¼ inch	21 50	.....
1½ inch	22 00	.....
1¾ inch	23 00	.....
2 inch	22 00	17 00
2¼ inch	26 00	18 00
2½ inch	30 00	20 00
3 inch	34 00	25 00
3¼ inch	43 00	27 00
3½ inch	47 00	28 00
4 inch	58 00	35 50

Pig Iron—The demand for pig iron is much better, and the coal strike is largely responsible for this activity. Several users are getting panicky and feel that non-union miners may decide to walk out en masse thus tying up activities. So, in order to play safe, they are ordering material, where a week ago they declared they were out of the market entirely. This has had a stiffening tendency, and price cutting is not so much in evidence. One firm stated that they secured more orders last week than any other week during this year. The price is firm at $27.15.

Non-Ferrous Metals—This market remains stationary, though weak. The consumer shows no interest, and the following are present quotations:

Lake Copper	17 00
Electric Copper	17 00
Castings, copper	16 50
Tin	34 00
Spelter	7 25
Lead	6 75
Antimony	8 00
Aluminum	26 00

Scrap Metals—This market shows improvement although prices have not advanced. There is a more optimistic tone throughout this section, and dealers expect further improvement shortly. Red brass is stronger but yellow metals are still weak with practically no demand. White metal also remains quiet. Steel scrap is much stronger, and the mills are now in the market, but only for a limited tonnage. However, dealers believe that the mills will soon find they are short, and feel that once this takes place, prices will advance. Cast iron remains quite firm, and dealers refuse to take orders at less than prevailing prices. Following are present quotations:

Copper, light ..... per 100 lbs.	8 00
Copper, crucible	10 50
Copper, heavy	10 50
Copper wire	10 50
No. 1 composition ..... 6...	8 50
New brass cuttings	6 00
Red brass turnings	6 00
Yellow brass turnings	4 75
Light brass	3 50
Medium brass	4 50
Scrap zinc	3 25
Heavy lead	4 00
Tea lead	3 00
Aluminum	10 00
Boiler plate, per gross ton	9 00
Heavy melting steel	10 00
Axles (wrought iron)	16 00
Rails (scrap)	10 00
Malleable	11 00
No. 1 machine cast iron	16 00
Pipe, wrought	6 00
Car wheel	16 00
Steel axes	15 00
Mach. shop turnings	6 00
Stove plate	14 00
Cast boring	5 00

Machine Tools—Several dealers report a fair amount of business, but nothing of importance. The tools sold cover a large field, and while in the total they are not too bad, there is still room for decided improvement. Enquir-

ies are numerous, and several dealers are expecting some good things to break very shortly. Competition is keen and everyone watches the other closely. This is decidedly a buyer's market, with every advantage his way.

Small Tools and Supplies—Things remain much the same. No price changes have taken place, and although this has been a poor week for some, others say they find no difference. Whether April will be any improvement over March is questionable, but the rest of the month may show up to better advantage. If not, the total will be about the same as last month if not a little lower.

Oils and Grease—The demand for oils, greases, waste, steel pipe, and other general lines, remains the same. Prices in steel pipe have stiffened still further and only extended delivery can be secured. Quotations on the above mentioned lines follow:

OILS AND COMPOUNDS

Castor oil, per lb.	34½
Royalite, per gal., bulk	21
Palacine	24
Machine oil, per gal.	33 00
Black oil, per gal.	17 50
Cylinder oil, Capital	61 50
Petroleum fuel oil bbls., net	9 90
Pure turp., single bbls. gal.	1 35
Linseed oil, raw, single bbls.	1 00

Montreal

April 19

THE GENERAL business situation has improved somewhat during the week, but aside from this, few changes can be reported. Looking ahead there appears to be many matters in the air that may directly affect local conditions in the near future. The opening of navigation has led to a second increase. Sheets, wire and several steel commodities have been rather active. Contractors are making excellent headway in their building operations, these consisting largely of apartment buildings and structures to be used for the dual purpose of business and residence. Manufacturing has not improved to any marked extent, except in a few specialties. Contract shops are fairly busy with spring repair work but the army of unemployed has not yet been entirely absorbed although the number is growing somewhat smaller.

Local longshormen are objecting to the new scale of wages offered by the harbor commission, and what the outcome will be, is uncertain. Few price changes have occurred, but several upward revisions are forecast.

Iron and Steel—Structural shapes and bars for merchant use have been moving fairly well, but there is still plenty of room for improvement. The present small volume of business being handled is considerably better than for some time past. Plates are the most sluggish of all steel items on the local market, but sheets are in good demand, especially galvanized wire, bars, etc., are moving better than last week and prices and quotations in all lines are firm, increased quotations being looked for shortly. Galvanized sheets are much firmer in British markets and locally, in importing these sheets with river navigation in full swing, the inland freight will be saved.

American quotations to local houses are also very firm. American mills in the middle west are reported to be working from 70 to 75 per cent. capacity. Eastern mills are not so busy, as they have largely confined their efforts to producing lines that are not in as great demand as the products of mills farther west. This has a tendency to create a very firm tone locally, and to eliminate all quotations for future delivery. No changes in prices have been made, and local quotations are as follows:

Iron bars	2 75
Steel bars	2 75
Reinforcing bars	2 75
Steel hoops	3 75
Tire steel	3 00
Spring steel	6 00
Band steel, No. 10 gauge and 3-16 in. base	3 25
Small shapes	3 00

Pig Iron—There appears to be a firm conviction that local quotations on pig iron will be advanced shortly. Some firms have already withdrawn their prices and are accepting orders only when they have been submitted to the various head offices. No. 1 iron is still quoted at $29.80 but orders are only accepted by the producers. No iron will be sold for delivery beyond the end of June, and when these new features were announced the latter part of the week, many firms placed orders for advance. These orders do not represent increased consumption as foundries are still very quiet but it looks as if the rumoured advance will result in increased business. Stocks are very low in all quarters and more or less business will undoubtedly be booked in the next few weeks. It is stated that several Buffalo producers have withdrawn quotations, and that others have advanced the price one dollar per ton.

Machine Tools and Supplies—Little or no improvement is noticed in iron working tools. There does not appear to be any immediate prospect of increased sales, the demand for some time past has been for small sizes, and for single machines. Prospects for large machines, or for batteries of tools are not in evidence, and every order is very aggressively sought, the tendency being to shade prices. Wood working tools are in somewhat better demand, and supplies continue to move fairly well, although most purchasers are still operating on the hand-to-mouth principle.

NonFerrous Metals—Quotations on practically all metals have been advanced during the week in sympathy with British and Foreign Markets. Still, there is no improvement in business locally. Lead and zinc are very strong. Tin is firmer, but it is not thought that this condition will hold. The tone is better, however, increased business is anticipated. Following are the local quotations:

Lake Copper	16 75
Electric Copper	16 50
Castings, Copper	16 25
Tin	35 00
Lead	6 75
Spelter	7 25
Antimony	6
Aluminum	23 50

Scrap Metals—No improvement has occurred in the scrap metal field. The fact that ingot metals have strengthened may create a better demand, business locally has not shown any very marked improvement as yet, and some even doubt whether the strengthening tendency of ingots will influence scrap until business picks up in the foundries.

Copper, light per 100 lbs.	8 00
Copper, crucible	10 50
Copper, heavy	10 50
Copper wire	10 50
No. 1 composition	8 50
New brass cuttings	6 00
Red brass turnings	6 00
Yellow brass turnings	4 75

Steel axes	16 00
Mach. shop turnings	4 00
Stove plate	16 00
Cast boring	8 00

Pittsburg

April 19

SPECIAL to Canadian Machinery—The coal strike is affecting the iron and steel industry more than was expected, because there has been a considerable amount of striking in non-union fields, particularly in Western Pennsylvania. Something of this sort was expected, but not nearly as much as has occurred. The union coal strike was expected to last several months, and what was thought to be sufficient provision was made against it. In particular, the strikes in the lower Connellsville region affect iron and steel, because normally, coke as made in the Connellsville region just as the coal is mined, is shipped as fast as drawn from ovens, and used by blast furnaces practically as received there being no stocks.

There have not been many strikes in the Connellsville region, or "old basin," but the lower Connellsville or Masontown field is nearly all down. Normally, the Connellsville region has more coke production than lower Connellsville but the former is largely a Steel Corporation affair, the merchant ovens be-

ing located largely in the latter mentioned territory. The Steel Corporation has partly made up for its loss in production in the lower section by starting additional ovens in the Connellsville but even the corporation has had to bank or blow out a few blast furnaces, perhaps half a dozen or more.

Pig Iron Demand:—Not many merchant furnaces have had to bank thus far, but there is danger that many will have to do so, and as they have pig iron obligations already, they have been withdrawing as sellers. Consumers on the other hand, appear to have discovered suddenly that they need iron and are not particular as to the price. Foundrymen who a month ago could not be coaxed to buy pig iron are now sending in orders, with the price space left blank.

No regular pig iron market is quotable, but prices would be not under $21 for Bessemer, $20 for basic and $21 for foundry, f. o. b. valley furnaces, or $1.50 higher on Bessemer, $2 higher on basic, and $2 higher on foundry, than the market ruling a fortnight ago. A small part of the advance in basic and foundry was reported a week ago, but the $21.50 figure given for Bessemer was an error, as the market had been $19.50 for quite a while.

Steel Supplies:—The turnover in steel products is considerably decreased. Part of the decrease is due to the reserve of sellers, exemplified chiefly by their stiffening up in prices, while part is due to buyers, who had undoubtedly been buying more freely in February and March than would have been the case if no coal strike had been expected. Undoubtedly consumption of steel has been increasing, but it is inconceivable that consumption should increase in three months in the way production has increased. In the last week of December steel ingots were being produced at less than 18,000,000 tons a year, while on March 31 the rate of production was in the neighborhood of 36,000,000 tons.

On the other hand, some buyers of steel seem to have been drawn into the market by the coal strike, but this disposition to buy on account of the coal strike is not noticed in steel to anything like the extent it is seen in pig iron.

The remaining independent wire mills have advanced nails, staples and barb wire $2 a ton, while the American Steel and Wire Co., has not yet taken action. It is expected that it will eventually advance. The advance that seems to be in progress does not involve plain wire or wire fence. The market is quotable as follows: Plain wire, 2.25c; cement coated nails, $1.90 to $2; wire nails, $2.40; to $2.50; polished staples, 1.55c to 1.65c; galvanized barb wire, $3.05 to $3.15; wire fence, 68 per cent off list, in carloads.

Bars, and structural small shapes are up $2.50 a ton, but attractive orders might still go at almost the old figure. There is no buying in sheets, as buyers have ample opportunity to cover before the $3 a ton advance that occurred early this month. It is said that the advanced prices are being firmly held, $2.40 for blue annealed, $3.15 for black, $4.15 for galvanized and $4.50 for automobile sheets.

Tubular goods are going fairly well at regular list prices, there now being little shading. Hoops are firm at $1.90 and it is said bands are commanding practically the same base price. Strip mills have advanced price, $2 a ton on hot rolled to $2 and $3 a ton on cold rolled to $3.65. The mills have a considerable tonnage of business on books at old prices.

Coal Strike Prospects:—The Connellsville and lower Connellsville regions were supplying coke to make between 20 and 25 per cent of the country's pig iron, and a large part of this supply has been shut off, possibly between one-third and one-half, while coke supplies elsewhere are menaced to a slight extent. Some of the by-product coke plants are well stocked with coal, but those that were depending chiefly on non-union coal are not so well stocked.

Up to writing there has been no recession in the striking in non-union fields, but the strikes have made little if any gains in the past few days. The Connellsville coke workers have always been strong for observing religious holidays, and there have been times when the Easter group of holidays made coke scarce for a short time. The operators have thus far made no effort to get their plants into operation again, but are now beginning, and it is possible that within a week or two strikes will be less prevalent.

The strike as a whole is divided into two parts. The trouble at the union mines was expected all along to last two or three months, some observers expecting it to be late in the Autumn before it was entirely settled. Then there are the non-union strikes, which are quite unlikely to last long. The union miners are quite accustomed to striking, having had one pretty regularly every two years for a long time as the biennial scale came up for adjustment.

Since the war they have thrown in two extra strikes. The non-union workers, on the other hand, are not accustomed to striking, and their trouble will probably be over long before the union strike begins to come to a head. While the United Mine Workers are back of the non-union strikes, they have no funds to pay benefits even to their regular members, let alone to new members whom they have taken in at $2 apiece, it being reported that in some cases they cut the price to $1. It seems that they have spent very large sums of money in the past year or two in their efforts to unionize certain fields in West Virginia.

TAPPING SQUARE THREADS

(Continued from Page 23.)

chronised with a slap on the desk, "Let's try."

With all ceremony the drawing was forwarded to a well known tap maker for criticisms and prices. They compromised with the suggestion that we use four taps embodying the same idea that I suggested using on the single tap. While they had been making taps for years and knew what they were talking about, I had some experience in the world and didn't see why they did not agree with my idea 100 per cent; finally I agreed to the change.

After several weeks elapsed, the taps were delivered to the manager's office for inspection. They looked beautiful; Bill picks up one and squints doubtfully down the flutes; I didn't need to look at them, I knew that they were going to work, all that I did was to stand with folded arms and await. The map of Missouri was spread on Bill's face as he asked, "Will they do the trick?" Being the father of a great idea that was going to plant me upon a pedestal, I awaited the comments from the manager. Sizing me up and down, then looking at the cost sheet again he then swung his feet up onto the desk and drew the Derby down over his forehead and replied, "I'm on the fence." At that Bill gathered up the taps and calling to the others to follow, went down the steps to the shop. He handed over the taps to the straw boss of the drill presses with instructions to tap some nuts. I felt that he gave the strawboss a wicked wink as he told him to use plenty of lard oil and to handle the job with all care at his command.

The machine was set in motion, tap after tap oozed its way through that nut until finally the last one produced a perfect nut. Bill grabbed the nut; the mechanical engineer looked in one end at the same time the manager was squinting in the other. Glowing in my victory I did not wait to see it, I wandered among the other machines nearby until Bill aroused me from my jubilant dream by calling "Hey Jack, we have several nuts to tap yet; stick around." By the time I had reached the machine the second tap was squeaking its way through the other nut; the third tap was started in the hole; half way through it clicked. If that story about the heart being up in the throat is all bosh, take it from me that my throat was down around my heart. Finally the fourth tap was started upon its sad journey. Alas! a grind, then a creak, then the inevitable usual scatter to the four winds of that shop. The main supporting pillar of that memorable castle being erected in my behalf had maliciously been withdrawn thereby tumbling the dominoes and dice of the superstructure to the mercies of gravity as the manager looked at me and smiled in that way known to know one but him and myself.

SELECTED MARKET QUOTATIONS

News From the Industrial Field

INDUSTRIAL NEWS

The Red Wing Quarry Co., dealers in stone, granite, stucco, etc., are considering locating in North Bay.

The new library building for Queen's University at Kingston will be started this fall. The approximate cost will be $350,000.

A report comes from Sydney that work on the Imperial Oil plant station at Baily Point, Cape Breton, is to be started shortly.

An addition to the factory of the Hamilton Cotton Co., costing $18,000 has been planned for. Stuart and Sinclair have the contract.

A salt refining plant is to be built at Courtright, Ont., by the Diamond Crystal Salt Co. of St. Clair, Mich., at an estimated cost of $50,000.

Construction work has been started on the new buildings being erected by the Fisher Motor Co. and the Canada Electric Castings Co. of Orillia, Ont.

Harry G. Dalton, of Pickands-Mather Co., ore refiners of Cleveland, Ohio, will succeed the late Senator John Milne as a director of the Steel Co. of Canada.

The Cosmos Cotton Co., at Yarmouth, N. S., has purchased several lots of land north of their large brick warehouse on Water Street, North Yarmouth.

The contract for the construction of a cooling plant for Swift Canadian Packing Co. of Ottawa, has been awarded to Joseph Robert at an approximate cost of $10,000.

Construction work on the new extension to the Port Arthur plant of the Provincial Paper Mills has been started. The cost of this addition will be in the neighborhood of $1,500,000.

The annual meeting of the Nova Scotia Mining Society is to be held at Sydney, N. S. May 16th and 17th and will be the first annual meeting to be held at Sydney for four years.

The schooner Kaduskak is loading lumber for Barbadoes. The timber industry of Nova Scotia was very dull this season. The number of men in the woods was smaller than for years.

At Carleton, Yarmouth County, E. F. Beeler has erected a lath and shingle mill, and contemplating possibilities of extension when the mill has gotten well into operation, an adjoining property has been purchased.

The E. B. Eddy Company sawmill at the Chaudiere opened Monday morning for the season's operations. Seventy-five men were put to work with the understanding that the number will be increased in a few days.

G. A. Owens has been appointed to supercede H. O. Shepard (transferred) as roadmaster of the Shore Line subdivision of the C. P. R. and the St. John terminals, with headquarters at St. John. Appointment is effective from April 1.

The contract for the erection of a new convent at Almonte has been let to A. C. Gilmour of Almonte, the work to be commenced as soon as possible. Completion is expected by Sept. 1. Messrs. Brodeur & Pilon of Ottawa are the architects.

The Westboro-Nepan High School Board has four sites under consideration for the erection of a new high school. Plans for the new building are practically complete and once the site is definitely decided upon tenders for the work will be called.

It is interesting to note, in connection with Canada's export trade developments that the Indian Government in the East, in calling tenders for a year's supply of lumber for packing cases, has specified Canadian spruce as the material required.

A. G. Milton, Ontario representative for the George Ellison firm in Birmingham, England, reported this week that business in their line is fairly brisk and that even better business is in sight. Their line includes electrical appliances and accessories.

Mr. Lennard of the Lennard Machine and Tool Co., 99 King St. W., Toronto, reported to Canadian Machinery, that until quite recently his plant has been closed down, but now reports a revival of business in their line, that of tooling parts for automobiles.

William Esmond, of Cardinal, Ont., has been instructed to proceed to France in the interests of the Corn Products Co., of New York. He will have charge of the installation of machinery in the new starch factory the company is erecting in the outskirts of Paris.

Building of two normal schools for girls, one at Beauceville and the other at St. Jerome, in the county of Terrebonne, has been ordered by the Quebec government. The estimated cost of these buildings is $100,000 each. Tenders will be called for almost at once.

At Amherst, N. S., industrial conditions are reported improved. The Canadian Car Co. have about 275 men at work on railway freight-car reconstruction and the Maritime Coal and Railway Co. are working full time, though the Woollen Mills have reduced their staff.

Toronto University is planning the erection of four new buildings and a requisition has been forwarded to the Provincial Government. The plans include a new Forestry building, botany and Administration buildings, a Woman's building, and additions to the heating plants.

A sliding scale rate which will run from sixty-five to eighty cents per hour instead of a flat rate basis which is now in effect, will probably be offered to members of the electricians' union of the city. Under the present agreement which expires May 1 the men received 80 cents an hour.

Forty-five cents an hour, as from May 1, was the unanimous award of the board of arbitration in connection with the building laborers' dispute. In addition the board recommended that a nine-hour day shall be worked and all time over this be paid for at the rate of time and a half.

At a meeting of the Civic Hospital Board held last week it was decided to call for tenders for masonry, brick and carpentry work in connection with construction of the new main buildings of the new hospital. It is expected that more tenders will be called for within two or three weeks.

The Avon Power Co. has received authority to proceed with development of hydro electric power at Avon Falls. Engineers and contractors have gone over the site for the dam. The first contract will be for the dam and a canal of 1,750 feet across a point of land to increase the head of water.

Word comes from Newfoundland of a silver find at Vernon's Island, Placentia Bay and W. H. McKay, mining expert, who has arrived at St. John's with samples of ore, showing not only silver but iron and lead, thinks there are evidences of another Cobalt in the district. A contract has been entered into for shaft sinking and other preliminaries to mining.

The Minister of Finance recently received a delegation from the Dominion Retail Merchants Association and the Automobile Merchants of Canada. The refund of luxury taxes upon automobiles to the amount of the loss not borne by the manufacturers was urged. Hon. W. S. Fielding promised the government would give careful consideration to the representations made.

Toronto Furnace Co., formerly the Toronto Furnace and Crematory Co., 111 King St. East, have dropped the crematory department of their business and are moving their head office to 35 Golden

What Can We Do For You?

If you are, at any time, confronted with troubles in your machine shop, do not hesitate to consult us. Both our inside and outside men are fully qualified to tackle any problem that may arise, and, while none of them pretend to "know it all," the breadth of their experience and our cumulate knowledge gained by intimate connection with manufacturers in Canada, United States and Great Britain places us in a position to render service second to none. What can we do for you?

The A. R. Williams Machinery Co., Ltd.

64 Front Street W., TORONTO

HALIFAX ST. JOHN MONTREAL WINNIPEG VANCOUVER

If its Machinery—Write "Williams"

Ave., where they have a strictly up-to-date foundry. In addition to manufacturing a full line of hot and warm air furnaces they will do general jobbing in heavy and light machinery castings for which they are fully equipped.

The Great Manitou Park Co., and the French River Navigation Co. have amalgamated under the name of The French River Park and Navigation Co. Provisional directors are Messrs. M. J. Wallace, F. A. York, E. A. Doan, L. Banner and T. H. Noble. The company will give a better service to the island which it is hoped will become a popular summer resort. Already a number of persons have signified their intention of building summer cottages there.

Industrial and constructional activity in the district of Sudbury is showing great improvement. Unemployment has been quite pronounced during the winter months but this condition is changing with the advent of warmer weather and men are being placed at work in many lines.

The patents and good will of the "Jack Frost" Electric Refrigerating business, formerly carried on by the Toronto Laundry Machine Company, of which the late John O'Neill was president, have been purchased by the "Jack Frost" Ice Machine Company, Limited, Toronto, with an authorized capital of $1,000,000.

The Sun Life Insurance Co., will soon commence to demolish the old Knox church in Montreal, in preparation for the construction of a large addition to their present headquarter's building. The aquisition of this property was included in the original plans, but until recently ample room was available in the existing structure.

It was announced recently that a built-up Barrett specification bonded roof will be installed on the new Mount Royal Hotel by the Carmichael Waterproofing Company, of Toronto, which has been given the contract for the roofing and sheet metal work to be used on the building. The roof will be approximately 70,000 square feet in size.

The International Nickel Co. has announced a new price list on nickel, monel metal and nickel specialties, effective April 1, showing a marked reduction from previous quotations. Nickel shot, ingots and electrolytic are reduced 5 cents a pound and hot rolled rods 10 cents a pound. Cold drawn rods are 12 cents a pound lower at 60 cents a pound.

Within the coming year it is expected that another imposing edifice will be added to the already fine collection of buildings in Kingston, Ont. A nurses' home will be erected in connection with St. Joseph's training school for nurses of the Hotel Dieu Hospital. It will be of stone, five stories in height, and dimensions 100 ft. x by 40 ft., and will include class rooms, demonstration rooms, and a large assembly hall in addition to accommodations for the nurses.

Negotiations have been successfully concluded whereby the city of Belleville, Ont., will secure another American industry. The new firm, The American Optical Co., will commence operations with 300 men, but ultimately will increase this number to nearly 700. The Canadian branch at Belleville will supply the Canadian trade, and also the large export business of the company, which has been handicapped of late by the friction caused by the high American tariff.

According to a statement made to Canadian Machinery by Louis H. Bean, vice-president of Dwight P. Robinson & Co., the volume of industrial construction has been showing gradual improvement. He states that:—"An increasing demand for goods is gradually taking up the slack in available manufacturing space and many industrial companies are now proceeding with new plants and extensions, as indicated by new contracts we received during the month of March."

The following are the names of companies recently incorporated under Dominion charters, with head office, capitalization, and name of one director:

Grant Brothers Construction Co., Ltd., Ottawa, $200,000, Alan G. McDougall; Manganese and Steel Foundry, Ltd., Sherbrooke, $25,000, Frederick S. Pugg; Northern Architectural Iron Works, (Montreal) Ltd., Montreal, $40,000, John G. Frost; La Compagnie Electrique de Rockland, Ltd., Rockland, $100,000, Andrew T. Thompson.

A bill to extend the accident-prevention effect of the Workmen's Compensation Act is now before the legislature and has received its first reading. The object of the bill is to recognize manufacturers who were trying to protect their workmen and to penalize those who were careless and this could best be done by a rating that would give a lower rate to the employer with the most modern protective equipment and the lowest accident ratio, and imposing a penalty rate on others.

In a statement recently made by Hon. W. C. Kennedy, Minister of Railways, it was shown that less than one-third of the work on the Welland Canal had so far been completed, and that the cost to date had been upwards of twenty-six million dollars. It was pointed out that if ample funds were available for the completion of the work, the canal would be ready for traffic during the year 1927. Work to be done this year includes the construction of locks on Section 1, 2 and 3, and excavation upon Sections 1, 2, 3, 4 and 5.

The annual statement of the Pressed Metals Co. of Canada, showed the concern to be in a healthy condition. The past two months of this year was reported to have been the best in the history of the company and considerable new business was anticipated. Up until lately the automobile activities of the company have been devoted exclusively to turning out bushings for the Ford interests only, but other car manufacturers are interesting themselves in these products and large orders are expected. The production capacity now exceeds one million bushings a month.

Operations in heavier navigation circles commenced at Kingston April 11, with the clearing of the steamer "Keyport" from her winter berth. This steamer is the first of the "Key" line boats to finish overhauling and outfitting. The four other "Key" boats are being put into shape by gangs of mechanics from the Collingwood Shipbuilding Co.'s shops, who are working under the direction of mechanical superintendent Waller, of Montreal. Some of these vessels will carry coal for the Montreal Light, Heat and Power Company, their owners, while others will be busy in the grain trade.

Industrial consumers of coal in Ontario have shown no sign yet that they fear a shortage of bituminous coal, as a result of the strike that has been in progress since April 1. The situation has been remarkably quiet, as regards operators, miners and consumers. The Canadian situation is causing little comment. The general view is that the long notice given to consumers gave them an opportunity to secure adequate stocks, and that there is no occasion for worry for some time yet. The large industrial users of coal in particular have protected themselves against almost any contingency.

Great interest is being shown in the discovery of a new metal, non-ferrous in character, and known as "Virtu." The new material dispenses with electroplating, does not tarnish, and is considerably less than half the cost of stainless steel ware. Experiments are now proceeding in the steel works to decide whether the discovery can be applied for engineering purposes. Exhaustive tests have proved that the material can be rolled or cast. The inventors are hoping to prove that it can also be forged or hot rolled like steel, in which case it could be applied to a hundred-and-one uses in constructional trades, as, for instance, turbine blades, agricultural machinery parts, and motor-car fittings, which are particularly liable to corrosion through exposure.

Wettlaufer Brothers, Limited, head office 178-180 Spadina Ave., Toronto, with plants in different parts of Canada, are building a new and strictly modern foundry at Mitchell, Ont., to replace the one which they had outgrown. They manufacture a full line of builders' and contractors' machinery and equipment, specializing in concrete mixers and equipment for the production of concrete bricks, blocks, drain tile and sewer pipe. They find business exceptionally good, and report that they are planning some of the largest contracts in their history during the present season. The new building will add 12,000 square feet of floor space to their plant. They are contemplating additional machinery but have not decided as yet just what it will be.

J. E. Ray, trade commissioner at Manchester, Eng., stated, in a recent report that during the years 1919 and 1920, Canadian wire rods became better known and more fully appreciated than was the case formerly. The purchases from Canadian manufacturers rose from 13,342 tons in the former year to 25,962 in the latter. No statistics are available for the year 1921. Although the demand is not brisk to-day, Canadian makers should keep their prices before customers. It is hard to battle against European competition, but the writer is assured that the quality of two countries producing on the Continent is far from satisfactory. One firm in Manchester would like to receive prices from a first-class Canadian manufacturer. (Address can be obtained from the Commercial Intelligence Branch, Ottawa, quoting file T. C. 3-113.) Statistics covering importations of wire rods, iron and steel wire and wire nails into the United Kingdom in 1919 and 1920, together with the countries of origin, are on file at the Department of Trade and Commerce, Ottawa, copies of which may be obtained by interested Canadian firms on application to the Director, Commercial Intelligence Service.

OBITUARY

Albert Melish Wickens

After a brief illness of three weeks, A. M. "Dad" Wickens, passed away at his home in Toronto a week ago. Born in Brantford, he lived in Guelph for several years and on removing to Toronto in 1883 became chief engineer on the Globe, a position which he resigned on appointment as the chief engineer at the Parliament buildings. He was afterwards connected with the Casualty Fire Insurance Co., and for the past five years he has lived in retirement. As a member of the first technical school board he took an active interest in the establishment of the technical school, at which time he lived on Berkeley street. He was one of the founders of the Canadian association of stationary engineers, by the members of which he was familiarly known as "Dad." He was 80 years of age.

Charles Simpson Boone

Charles Simpson Boone, president of the C. S. Boone Dredging and Construction Company, Limited, died yesterday at his home, 142 Crescent Road, following a stroke. Ill-health had compelled Mr. Boone, who was in his 68th year, to give up active business life five years ago. Born at Oakville, Ont., on August 27th, 1854, he was educated in Rockwood Academy and embarked early on a commercial career. For many years the firm has carried out dredging and harbor improvement work, largely for the Dominion Government, on the Great Lakes, the most important undertakings having been at Collingwood, Little Current, in Manitoulin, the Canadian Soo and Port Arthur. At present the firm is engaged in work at the Chippawa Canal for the Hydro-Electric Commission. The late Mr. Boone, who was an extensive holder of downtown real estate, was a member of St. Paul's Church, Bloor Street, and a 32nd degree Scottish Rite Mason. His hobby was pictures, of which he was an excellent judge.

T. H. Rieder

Following an illness of about ten days, T. H. Rieder, president of the Ames-Holden and McCready Co., died last week at his home in Montreal. Mr. Rieder was born in New Hamburg, Ont., August 10, 1878.

He was educated in the public and high schools of Kitchener. He engaged in general store business with his father, 1892-1897; became stenographer for Kitchener Gas Company and L. Breithaupt estate, 1898, and gas and electric meter reader and collector, 1898-1900. He was bookkeeper and director of the Kitchener Rubber Manufacturing Company, 1900-1903. He or-

ganized and built and was managing director of the Merchants Rubber Company Limited, 1903-1906.

The Kitchener Rubber Manufacturing Company and the Merchants Rubber Company, Limited, were absorbed in 1907 by the Canadian Consolidated Rubber Company, Limited, at which time Mr. Rieder became vice-president and manager of both Kitchener companies. He was elected vice-pres. of the Canadian Rubber Company, Limited, 1908, directing all operations of the company. In 1915 he was made vice-president and general manager, and president and general manager in 1917. In the year 1919 he resigned from the rubber and felt companies to accept the presidency of the Ames-Holden-McCready, Limited, and its subsidiaries.

The contract to build the new St. Michaels Church in Leamington, Ont., has been let to B. Bondy of Chatham. The cost will be approximately $20,000.

The passenger and freight steamer Britannic of the Cornwall and Montreal Navigation Co. will go into commission on her old run between Montreal and Kingston on April 24.

The Canadian Government steamer "Scout" left Prescott Wednesday on the first trip of the season to place gas and spar buoys along the channel and attend to permanent lights.

The steamer Lakeport of the Peterson Steamship Lines, of Cleveland, which wintered at Ogdensburg cleared last Saturday for Thorold to load newsprint paper for the Chicago Tribune.

The four local lodges of the Independent Order of Oddfellows in Ottawa are uniting in the purchase of a site and the building of an Oddfellows' Hall. Plans have been left in the hands of a committee. The hall to be erected will be centrally located and will cost in th vicinity of $35.000.

The plant of the Ogdensburg Pulp Mills is **closed** temporarily on account of a lack of pulpwood. Several orders are on hand for the highest grade but the pulpwood necessary must be secured from a distance. The mill will resume operations as soon as the raw material is available.

The city council of Windsor, Ont., has asked the Ontario Power Commission to build an auxiliary plant in the Border Cities to furnish electric power when the line from Niagara Falls is down. The request was prompted by the three lightless and powerless days suffered by this section between March 30 and April 3.

The early days of April brought a gloom to Kingston industrial circles occasioned by the death of William Cook, for many years superintendent of the large plant of the Dominion Textile Co. Although Mr. Cook had been in failing health for some time, the end came as a shock to a large circle of friends in every walk of life. Besides his activities in the business and industrial world, the late Mr. Cook was a prominent figure in sporting organizations and a great booster for hockey.

The freight rate on soft coal from Detroit to Windsor will continue indefinitely at 80 cents a ton according to the reply of the Canadian Freight Association to the Border Chamber of Commerce. In 1915 this charge was 30 cents and the Border manufacturers have been seeking relief from what they consider an exorbitant charge. They will ask the co-operation of the industries in Niagara Falls, Sarnia and other border points in a further effort to have the "cross the river" rate reduced.

J. J. C. Bradfield, chief engineer for New South Wales, Australia, is in Western Canada and United States visiting firms who expect to bid on the Sydney Harbor cantilever bridge. He is scheduled to be in Walkerville, Ont., about April 28 from where he will go to Toronto, Ottawa and New York. He will sail for England in June. The Sydney bridge, while it has only a 1,600 foot clear span to 1,800 on the Quebec bridge will probably have a greater total tonnage of steel due to the fact that it will carry highways as well as railways.

Tenders will be asked within the next two weeks on three building contracts in the Border Cities, Ont., aggregating $180,000. The Windsor Council, Knights of Columbus, are to build a $70,000 club house behind their present quarters at 541 Ouellette avenue. The Separate School Board has sold debentures amounting to $80,000 to finance the construction of a new school on Drouillard road, Ford City, Ont. Tenders will be asked for about April 25. The school is to be ready for the fall term. The Beach Grove Country Club in St. Clair, Ont. is going to build a club house that will cost about $30,000. The contract will be let before May 1. Pennington and Boyd of Windsor are the architects on all three of these structures.

CANADIAN SCIENTISTS WILL TAKE PART

A number of Canadian representatives are to attend the International Science Conference to be held in Rome next month and at the conference a special effort is to be made to arrive at a uniform system of arriving at tidal data throughout the world. Dr. W. Bell Dawson, of the Tidal and Current Survey Branch, Naval Department, who will be one of the Canadian representatives, is known the world over as an eminent authority on tidal and current questions. Canada's investigations of tides and currents under his direction is stated to be in advance of most other countries. He will leave Ottawa for Rome to-morrow, it was announced to-night by the Naval Department.

TORONTO FIRM FILLING FRENCH ORDER

The R. Anderson Co., Toronto, have recently shipped to J. Herrburger, Paris, France, an 1,800 lb. Keyboard boring machine. This order was secured about three weeks ago.

CANADIAN FIRMS MAY SECURE CREDIT IN BRITAIN

Through a plan recently inaugurated by the British Government, Canadian municipalities or industrial corporations may obtain advances for undertakings to the extent of the value of British machinery or other materials purchased in this country for such undertakings. Thus, a Canadian city or town contemplating Hydro Electric developments may finance the purchase of the necessary plant in Britain through the medium of the British Government credit, or a responsible company may do the same in installing or enlarging its plant facilities. Guarantees to the extent of about $70,000,000 have been approved by the British Treasury for this purpose.

The Philip Gies Foundry, Kitchener, are placing on the market a line of machinists' vises, solid and swivel bases, in five sizes, 4-inch, 4½-inch, 5-inch, 5½-inch and 6-inch. The vises are nicely proportioned, yet have the weight to stand the rough usage that a vise is generally subjected to. The body is of semi-steel and the jaws and screw of tool steel. Beaver vises are the result of observation as to heavy-duty requirements in everyday shop practice.

EXAMPLE OF VERTICAL MILLING

(Continued from page 18)

unusually tough. This operation was performed in a locomotive shop.

The Cincinnati Milling Machine Co., practice what they preach, for in making their milling machine vises, they machine the bottoms of the vise bases on their own millers. They use their own all steel vises to hold the work, and two are placed on the work table. Thus, the operator loads and unloads during the time the cutter is machining the other base. Two cuts are taken, a roughing and finishing, and a base is completed every 4.3 minutes, against a former planing time of eight minutes.

Because a part has been machined in some standard manner for years, is no reason why it should always be completed the same way. The successful foreman is continually on the lookout for better production methods, and while vertical milling is not by any means always the solution, it has in many cases increased production, and reduced operating time in an astonishing manner.

The city engineer of Chatham has been appointed to the position of city manager. He will continue also to discharge the duties of engineer.

ATKINS METAL CUTTING SAWS

Present Conditions

Don't let present-day conditions worry you; everything is fundamentally sound. More economy is being called for, use

Atkins Metal Cutting Saws

Conditions are such that quality and quantity production is essential. The use of Atkins AAA Non-Breakable Hack Saw Blade and Frames, Circular Metal and Slitting Saws, Hot Saws, Cold Saws, Kwick-Kut Hack Saw Machines and Blades and Metal Band Saw Machines, will assure you of efficient, economical operation and give you quality and quantity production.

Foundries
Industrial Shops

You can establish a contact with prospective buyers by cultivating their business in these papers—each exclusive in its field—

CANADIAN MACHINERY AND MANUFACTURING NEWS—published weekly, serves the Machinery, Iron and Steel and General Metal-working industries, reaching proprietors, purchasing agents, business men, works managers, superintendents and foremen. All Canada's important manufacturing and metal-working shops are covered, machine shops, engineering plants, railway shops, iron and steel mills, farm implement manufacturers and, in fact, all kinds of shops where metal-working is carried on.

POWER HOUSE—published semi-monthly. It serves steam, electrical, water and gas power plants and refrigeration plants throughout the Dominion. It reaches plant owners, their purchasing agents and stationary engineers and firemen. It goes into the power houses of all general manufacturing plants, pumping stations, mining industries and railroads.

CANADIAN FOUNDRYMAN AND METAL INDUSTRY NEWS—published monthly. Serves all the grey iron, steel and non-ferrous foundries in Canada. Reaches owners, superintendents and foremen.

Good distribution of your product is desirable—good salesmanship is essential. Our proposition possesses possibilities that will be sure to interest you. Full information on request.

Why it costs less to clean Metal Parts with Oakite

LOOK at the drop of oil in the lower left corner. The central portion shows how a drop of oil emulsified by Oakite looks under a microscope that magnifies it 1,000 times.

Notice how the oil is broken up into minute globules. In an emulsion the particles of oil are constantly in violent motion. The adhesive nature of the oil has been destroyed. This explains why the oil so readily passes from the metal surface into the Oakite solution.

Emulsification is a physical action, and does not use up the Oakite. Hence a small quantity of Oakite will do a great deal of cleaning.

A plant that formerly used lye to strip enamel from metal parts now does as much work with Oakite in 15 minutes as it formerly did in 3 hours with lye.

Another concern that used soda ash adopted Oakite materials and is saving $83.52 a week.

Is speed a factor with you? Or are you particularly interested in cutting cleaning costs? We can help you, because Oakite cleans faster and better—and cleans most economically.

It incurs no obligation to haveafrien d-ly talk with one of our experienced Service Men. Find out what he can do. Out of his broad experience and ability you are sure to get some helpful ideas that are worth while.

Write us To-day.

ONE J. & J. TAYLOR SAFE, INSIDE DIMENsions 15 inches deep, 2 feet 6 inches wide, three feet 11½ inches high and fitted with a built in compartment. Price $250.00.

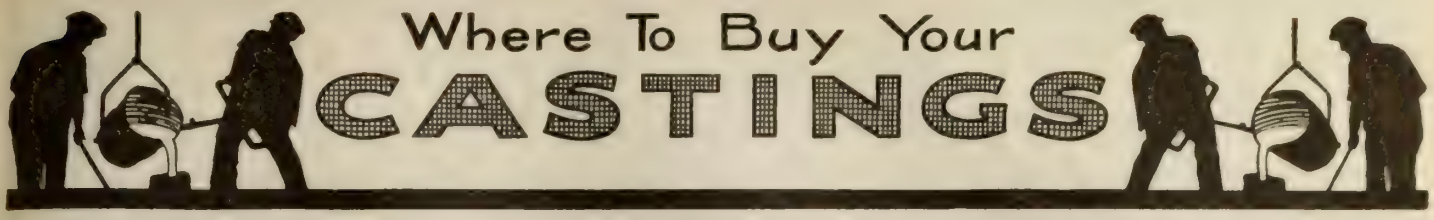
ONE J. & J. TAYLOR SAFE, 18 INCHES deep, two feet 9 inches wide, four feet five inches high, fitted with a steel compartment. Both safes are in good condition and can be bought at a price that will save considerable money to the purchaser. Price $200.00. Box 806L Canadian Machinery.

Machinery Wanted

Advertisements under this heading will be inserted once free of charge. Readers are invited to use this department when in need of equipment. Replies may be sent to box number, care of Canadian Machinery, if desired.

"It Pays to Advertise"

"One of the most persistent advertisers in the history of success was Robinson Crusoe. He knew what he wanted—a ship—and he put up an ad for one. He flung a shirt on a pole, at the top of his island; that, in the language of the sea, was plain to every sea-faring man.



"The circulation was small—there was no other medium—but Crusoe kept at it, despite the fact that he got no inquiries for a long time. He changed his copy—as one garment after another was frayed out—and in the end got what he wanted.

"Suppose Crusoe had taken down that signal after a time and declared 'Advertising doesn't pay,'—where would he and his story be now?

"Put up your signal and keep it there. Crusoe advertised under very discouraging circumstances. You've got a sure thing—it is only necessary to have the patience, persistence, and pluck of Robinson Crusoe—and the good ship 'Better Business' will tie up 'longside your pier."

Every Railway Engineer

Should Read
The Important Series of

LOCOMOTIVE *and* RAILWAY ENGINEERING NUMBERS

of

ENGINEERING PRODUCTION

The British Journal of Works Practice and Administration

MARCH 16th to MAY 4th
Inclusive

These numbers will deal fully with the production methods employed in the great British railway works, and all modern plant and equipment as applied to the requirements of the railroad will be described and illustrated.

Details will be given of the best practice in the railroad and independent locomotive shops of this country, also of works systems, every phase of the latest works methods being dealt with.

"Engineering Production" is Published Weekly, price 6d., and may be obtained through any newsagent or bookstall, or direct from the publishers, price 7½d. a copy, post free.

Subscription Rates: Great Britain, 32/6; Canada, 32/6; Other Countries Abroad, 36/10, per annum, post free.

Publishers: Iliffe & Sons Ltd., Dorset House, Tudor St., London, E. C. 4.

HINTS TO BUYERS

List of Directory of Dealers will be found above Advertising Index

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

BROWN & SHARPE

Nos. 4 & 6 WIRE FEED SCREW MACHINES

A Money Saver---even on Short Runs

We grow so accustomed to thinking of a Wire Feed Screw Machine as a good money saver on long run jobs that we often forget the economies it offers on shorter runs.

Suppose a dozen bolts are wanted in a hurry. Two factors must be considered—speed and expense. As it's a question of rapid, uniform production at low cost, consider the economies of running off this small lot on a wire feed screw machine.

In the first place, instead of cutting the stock into lengths, the uncut bar is placed in the rear end of the spindle. A turn of the wrist with a wrench adjusts the roller feed and automatic chuck to grip the proper size. One pair of chuck jaws to hold all shapes of stock, round, square or hex., is a great convenience.

Of course, there are no centre holes to drill. The chuck grips the bar securely; a centreing guide at the rear end of the spindle holds the stock in line with the spindle, relieving the chuck of unnecessary stress, and insuring firm support.

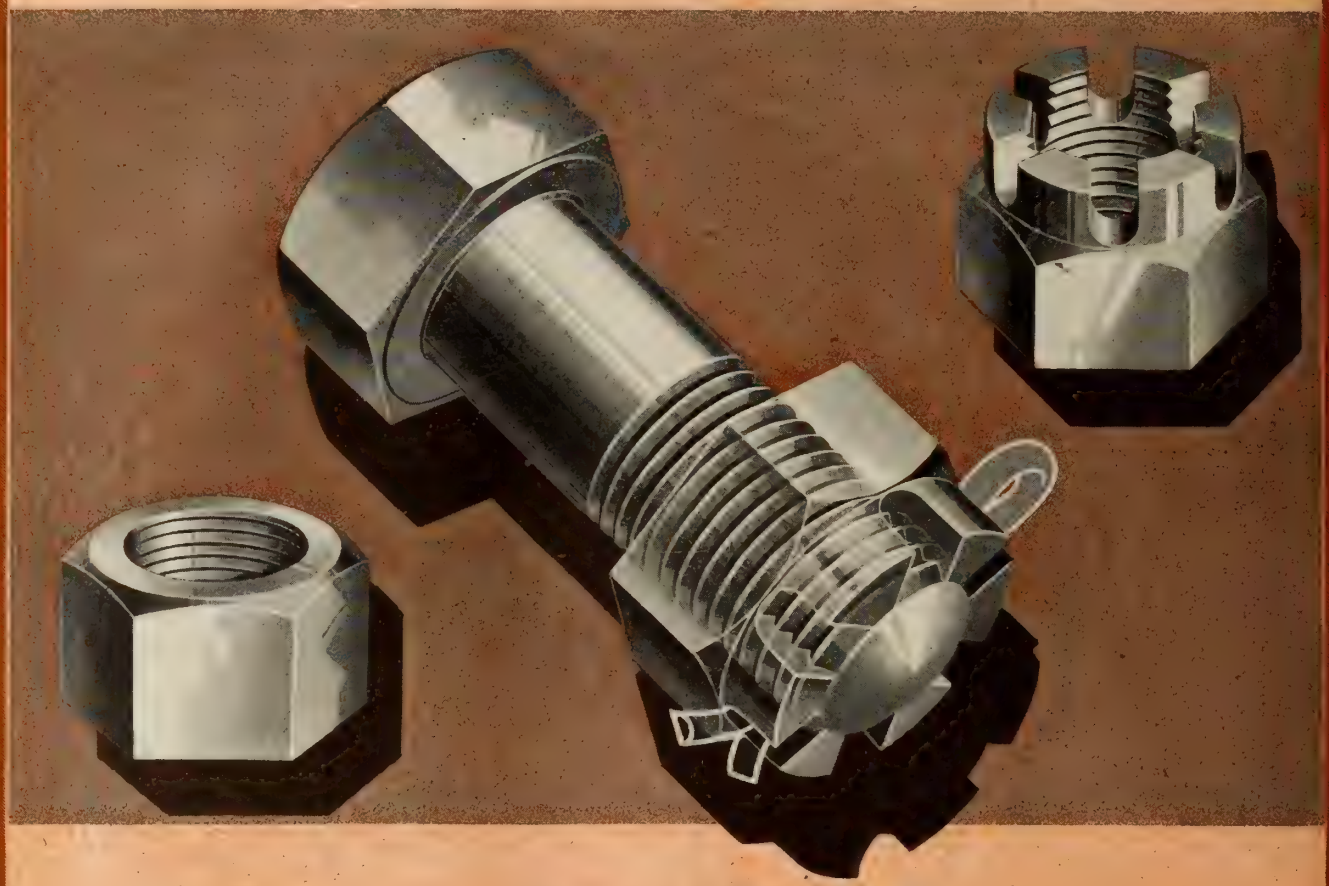
In operation the machine is speed and simplicity itself. One turret tool roughs out the piece. Then the finishing tool is swung quickly into position and turns the piece to size. And every piece will be the same size without bothering about tool adjustment.

Dies do the threading rapidly, accurately and uniformly, saving an extra handling.

When each piece is cut off by the cross slide tool it is finished, ready for use.

Have we suggested possible uses for a wire feed screw machine in your shop?

Our representative will be glad to show you how a Brown & Sharpe Wire Feed Screw Machine can help you save money on short or long jobs.



Write to-day for Catalog No. 22-G.

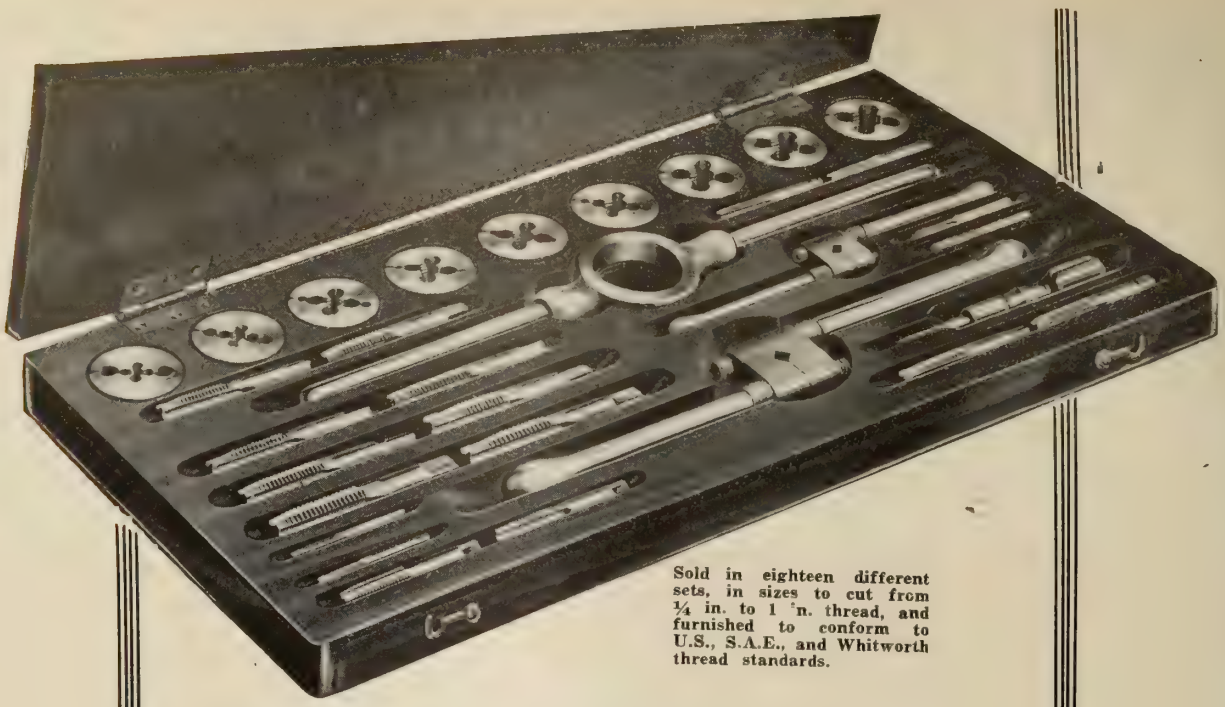
YOU pay your workmen well for their time and effort: don't waste this labor-element by keeping dull files in use.

A file ceases to be fully efficient as soon as it has *begun* to lose its keen-cutting edge.

Replacing it costs only a trifle, but means much in increased efficiency.

These brands, the standard for over 50 years, do not dull quickly:



Kearney & Foot - Great Western

American - Arcade - Globe

Made in Canada by:

NICHOLSON FILE COMPANY

Port Hope - Ontario

Sold in eighteen different sets, in sizes to cut from ¼ in. to 1 in. thread, and furnished to conform to U.S., S.A.E., and Whitworth thread standards.

PRATT & WHITNEY

Screw Plate Sets

These reasonably-priced sets of standard P & W taps and dies, consist of our regular product made up in various combinations to meet the requirements of the small shop, garage, service station and general tool-room.
They are unequaled for fast, accurate threading of all metals and will be found invaluable whether used occasionally or for every-day work.

The taps and dies that go into P & W Screw Plate Sets are of a high quality unusual in such general purpose outfits. The taps are all made with the famous "con-eccentric" land—an exclusive Pratt & Whitney feature—that permits their resharpening on the face of the cutting edge without change in size.

For Making
Perfect
Screw-Thread Joints

SMOOTH-ON

ELASTIC CEMENT NO. 3

A screw-thread joint made with Smooth-On Elastic Cement No. 3 will not leak, because the Smooth-On expands in metallizing and so closes up any defective places which otherwise would cause leaks; yet the joint may be taken apart when desired.

Smooth-On Elastic Cement is sold ready for use in paste form. It is applied to the screw-threads with a brush. Especially useful for high pressure steam or water joints, for ammonia joints, for coating flanged joint faces and for coating gaskets.

Send for our new Smooth-On Instruction Book No. 18. It illustrates and describes how to make perfect screw-thread joints and hundreds of other repairs. You will marvel at its contents. The book is **FREE.** Smooth-On Iron Cements are sold in 5-lb., 10 lb. and 25 lb. tins. Also larger sizes.

Dunlop Belts Respond With Efficiency, Economy and Long Life to All Uses.

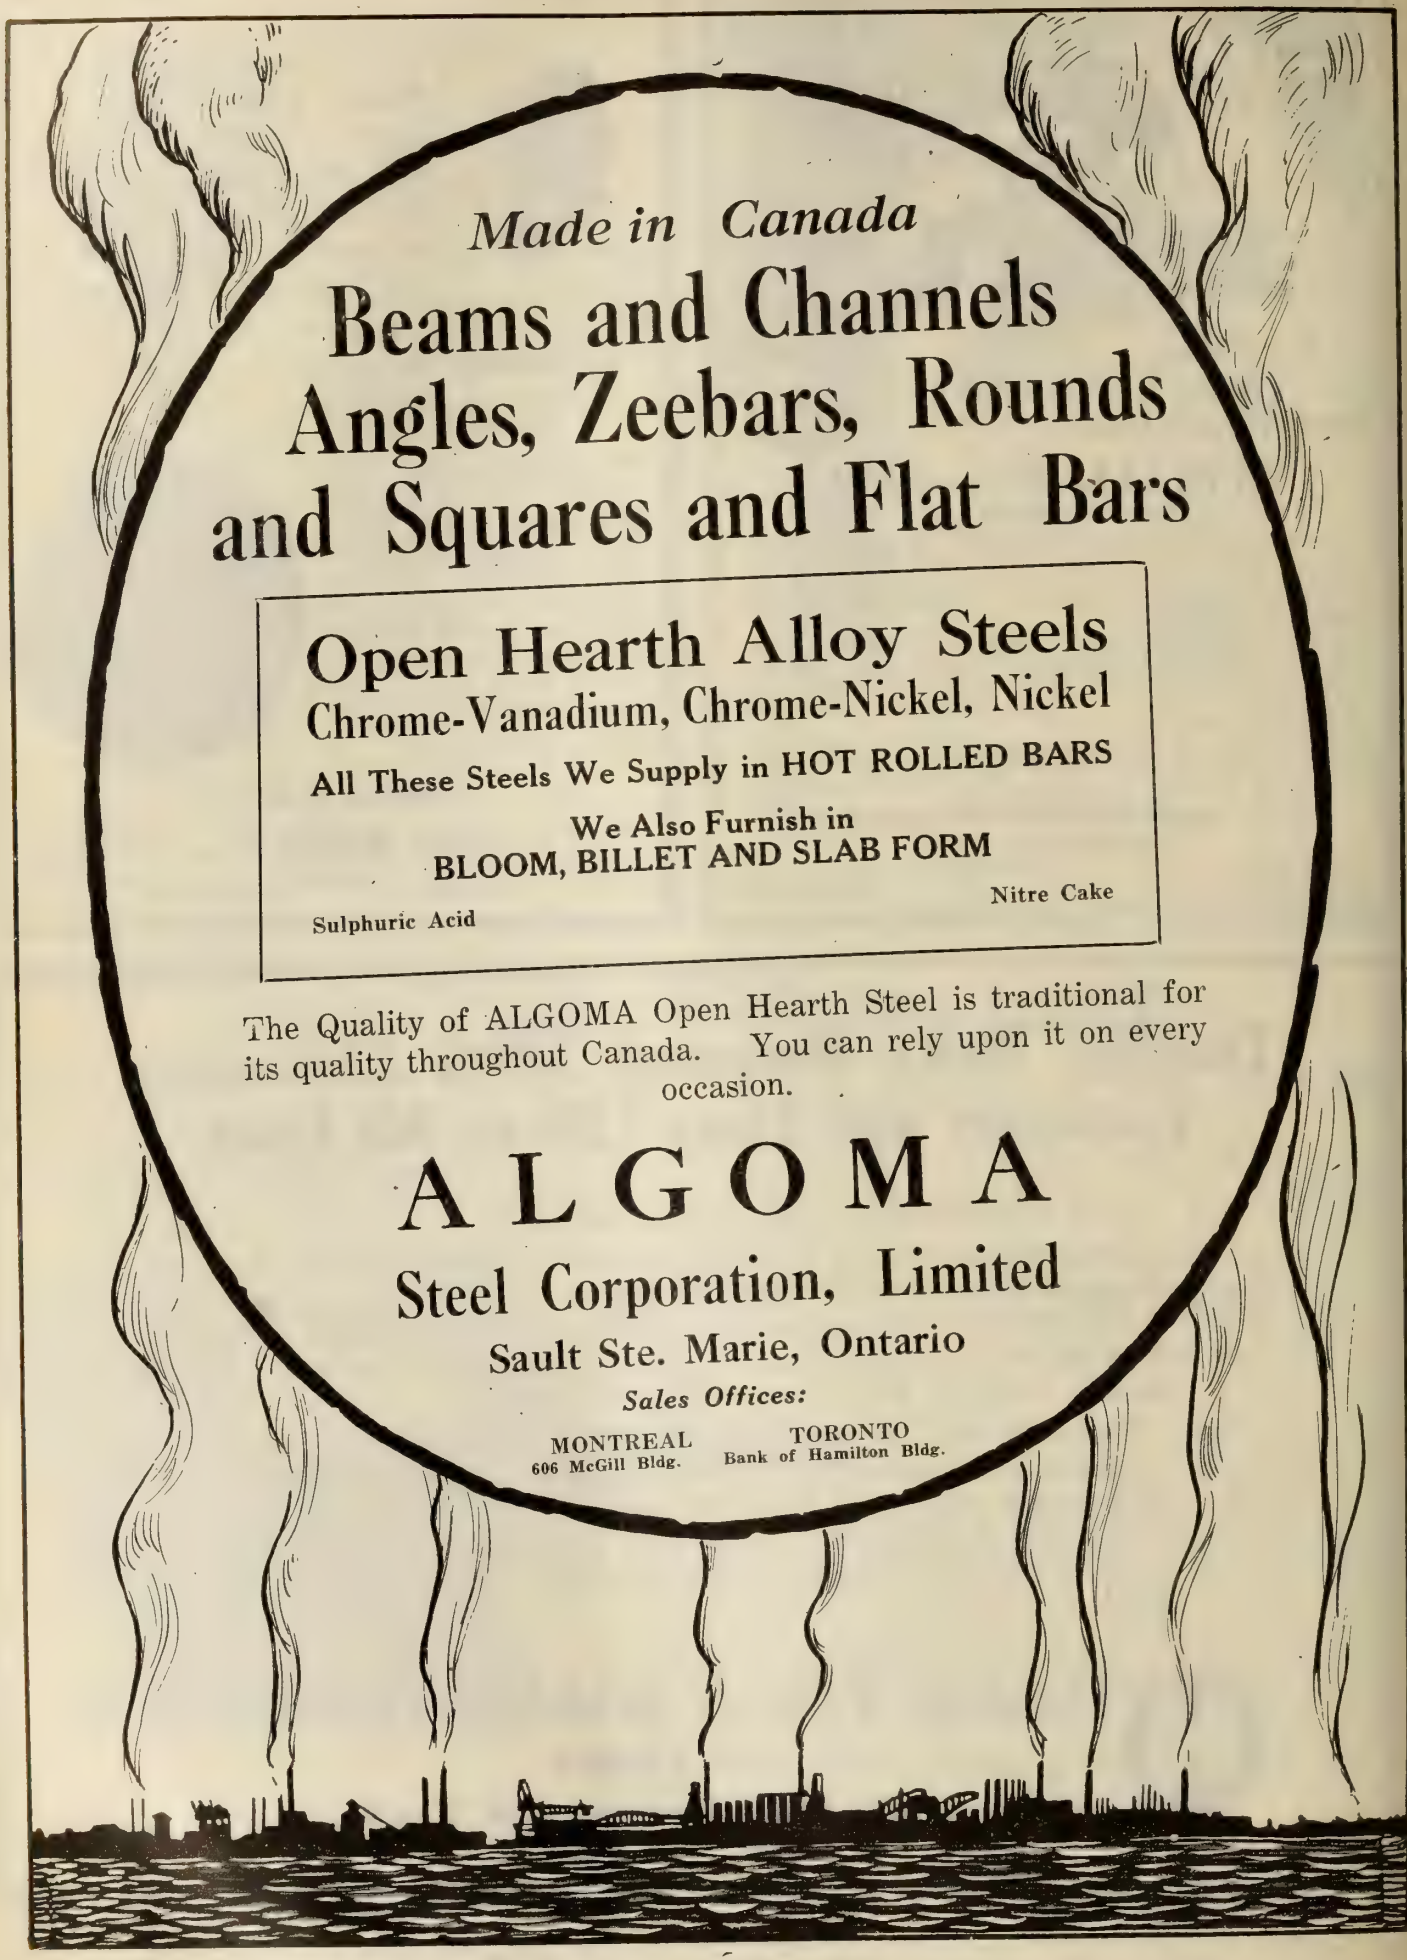
They are built with an eye to long service.

They save machinery by their ability to run smoothly and easily, yet they transmit the required power.

The special frictioned-surface of "Gibraltar RedSpecial," and the great flexibility of this Belt ensure close pulley contact. It masters straining drives and off-and-on loads.

Heat and cold, wet and dryness, do not affect it.

The Dunlop process eliminates stretch. This saves constant adjustments and undue waste of time.



For Belt Economy and Belt Efficiency use "Gibraltar RedSpecial" frictioned-surface. This Belt will adapt itself to any drive.

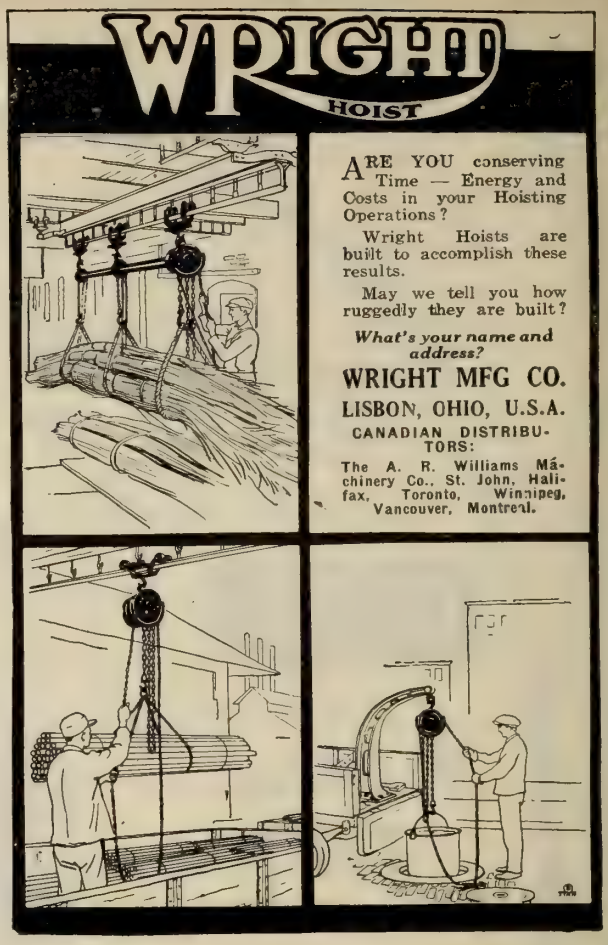
Announcing the

C.M.C.

4' Radial Drill

New design

The new C. M. C. 4 ft. Plain Radial Drill embodies the most modern features of Radial Drill construction.



Note that the controls are centralized. All thirty-six spindle speeds are controlled by levers mounted on the carriage, and the operator will have no occasion to leave his position to make adjustments. They are all under his hand.

Built for single pulley drive or constant speed motor drive. The speed of the initial transmission shaft is constant until after passing the frictions, giving as much power on the low speeds as on the higher, greatly increasing the efficiency of the machine.

Do You Read These Advertisements?

Every advertisement in this magazine is worth reading. It is the product of some concern that is using a modern method of making sales, viz., technical paper advertising, in order to present most effectively to you the leading features of its line.

These advertisers are making it easier for you to buy intelligently with the least waste of your time and theirs. They realize that a sales force can not replace this service at equal cost. They know that advertising is good business, for the manufacturer who does not advertise cannot save the cost of advertising. Consistent advertisers are progressive merchandisers. They are saving your money and their own; and it pays to do business with them.

Don't miss your opportunities. These advertisements are interesting. Many are distinctly instructive, and a glance through them every week will keep you posted on the latest developments for machinery equipment.

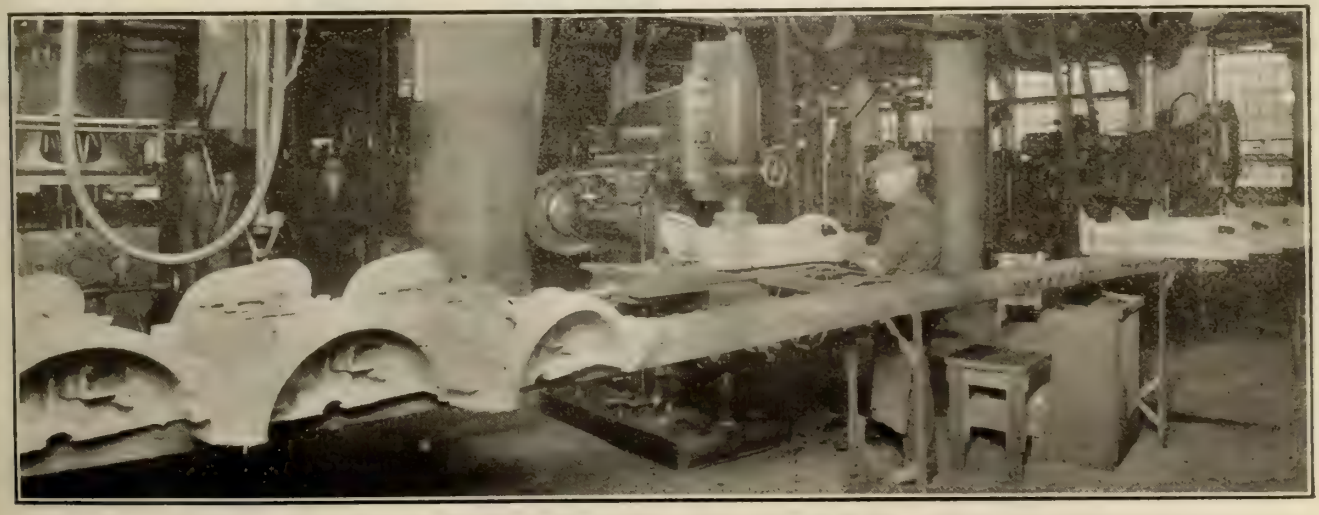
Inspection Methods That Have Proved Successful

See That Specifications are Correct—Incoming Material Should be Carefully Inspected Before Going Into Stores—Where Gauging is Most Effective—Co-operation of Departments

By H. ALTON



THE successful large shop always carries with it a more or less well-rounded-out organization, where we invariably find a well balanced inspection department. These inspection departments wor along certain well defined lines, being always producers of revenue indirectly, and directly a source of great satisfaction to the executives.

In the case of a small shop where the volume of work is not large we find the product is often of a variable nature, and even if an inspection department could be maintained, it could not work along hard and fast lines, as the work to be gauged or checked varied greatly. In such cases only a few general ideas can be suggested as it is more than probable that the details would have to be worked out separately. The chief engineer should see that the specifications for all material ordered are correct, and take steps to have these confirmed when the goods arrive. The engineer would prepare all blue prints, data, and specifications for the shop superintendent. Then from time to time the engineer should check all details as the manufacturing progresses. In other words the superintendent's duties would be to produce the article according to his instructions, and the duty of the engineer would be to check every point in a manner entirely independent of the shop superintendent, so that an oversight, omission, or error, could not fail to pass undetected. The sum and substance of this form of inspection is to have at least two competent individuals, working entirely independently of one another, check every factor and detail of the work, as it progressed through the shop. Of course, in larger shops operated on a production basis, a more definite description of the methods employed can be given. The experience of the writer in a shop of international reputation, will form the general basis of the data from which this article has been written.

Functions of the Inspection Department

The inspection department should be absolutely independent of, and in no way directly connected with manufacturing or production. In this way the department can be relied upon to exercise impartially its best judgment. It is not to be inferred that the inspection and manufacturing divisions should be antagonistic. That state of affairs would be extremely detrimental to the successful outcome of any business or plant. They should on the other hand, work in harmony but absolutely independently. It was found that several forms of organization work out successfully. In many cases where a general manager is an active and practical man, well informed about the business, and has a first class right hand man, he has taken over the active direction of all departments excepting say the sales and financial departments. Sometimes the term general manager, is changed to works-manager, managing director, or any one of several other appellations. Under this officer comes the following departments; engineering, purchasing, manufacturing and inspection. Of course these may be sub-divided further, other minor departments added, or some removed from the list, as special circumstances may determine. These departments in many shops are known by various names and often a rather complex organization is built up.

The inspection department has access to all engineering records and in addition receives specifications, blue prints, and all kinds of miscellaneous data from the engineering department. With this

These castings are thoroughly inspected before going to assembly department.

information it endeavors to keep the product up to the standard required, and to do this in a way that is efficient and interferes to the least possible extent with economic production.

Sources of Information

After it has been decided by the Board of Directors that a certain article is to be manufactured in quantities the engineering department prepares the specifications of the material to be used, suggests the machines, methods, tools, jigs and fixtures to be employed, etc. With this information the inspection department starts to function. We will endeavor to point out the various ways that inspection enters into the manufacturing, from the point where the raw material enters the shop to where it is shipped out as a manufactured article.

Incoming Material

As soon as a purchase order is sent out a copy of this order, without prices, should be delivered to the inspection department. A complete copy of the specifications, quantities, sizes, and all other information that would be of assistance in describing the material, should also be delivered to the chief inspector, if these details are not included on the purchase order. These papers should be filed so that they are readily accessible. As soon as any l. c. l. incoming goods are reported at the receiving department, before delivery is taken, the inspection department should be notified. In fact the inspection department should have complete jurisdiction over the receiving department. Packages should be carefully examined and if there are any signs of rough usage, or failure on the part of the package, same should be noted fully on the receipt given the carriers. At the same time, in connection with boxed and packaged goods, steps should be taken to verify, inasfar as it is possible, that the quantities agree with the quantities ordered shipped and invoiced. Sometimes goods are so packed that this is difficult, yet an experienced man can tell readily if a box of such a size is likely to contain half a dozen, or two dozen articles of a more or less perishable nature, the size of which is known. In attempting to describe these qualifications one is dealing with a rather abstract subject, but it can be readily understood that a little common sense applied along these lines will cause the elimination of more or less trouble. Following the receipt of such goods, same should be unpacked, checked in, compared to the specifications, or have these verified in-as-far as the situation would justify, and then if all the matters check up, the goods should be immediately checked in as to storage and a receipt obtained from the store-keeper.

In the case of incoming carload shipments the seal should be broken by the inspection department and all goods shoud be immediately checked in, as to quantity, quality, etc. Damaged goods or short shipments should immediately be reported and every step taken to establish a clear claim. Goods should be in their various storage warehouses or storehouses before the responsibility for them passes on to the store-keeper. Should it be found that it is difficult to check the material as to specifications without resorting to such highly specialized methods, as chemical analysis or tests of tensile strength, etc., it would be quite permissible to have such tests made, or to obtain a certificate that is above suspicion from a properly qualified authority who has made these tests for the manufacturers. If a certificate is obtained even then the acceptance of the fact that the goods are O. K. should be made under mental protest, as it were, and the goods carefully checked throughout manufacture. This is one of the cases where judgment will have to guide the chief inspector. Cognizance will have to be taken of the firm with whom the dealings have been made, and also the importance of the functioning of the goods in the manufactured article, and many other matters that it may seem expedient to consider. If any decision of importance has to be made in this connection, it should become necessary to inform the general-manager and he in turn would take up the matter with the engineering department. This step is necessary, because it is not the function of the inspection department to assume the responsibility of making any decision which should properly fall on the shoulders of the engineering department.

Railway claims figure rather extensively in the handling of many commodities and if shipments from a certain firm continue to arrive in bad order, whether from poor packages, careless packing, or other reasons attributable to the shippers it would be the duty of the inspection department to record this data and bring it to the attention of the general manager. A continuance of this practice would undoubtedly lead to a direct or indirect loss, of no small amount to the company receiving the goods.

Inspection of Articles in Process of Manufacture

The methods used in checking and inspecting articles in the process of manufacture are legion, and in the following paragraphs an attempt will be made to suggest ways and means that prove effective over a wide range of varying products that are commonly produced in our machine shops.

From the engineering department the chief inspector would obtain a full set of detail and assembly drawings of the part to be machined. Also an operation schedule would be provided showing the number of operations and sub-operations performed and how these were to be taken care of, what operations would be done with one setting, etc. Then, in consultation with the engineering department, it would be determined at what stages of the manufacture, gauging and inspection should take place. The ideal theoretical method would be to gauge every part from every machine immediately upon the completion of the operation. Practically, this cannot be done except in a few cases. Some products such as machine screws, studs, nuts, rivets, etc., being produced on automatics, specially tooled, are turned out in such quantities, and at a very rapid rate, that to gauge every piece would add over one hundred per cent. to the cost. Then again there is the product that may have one or more roughing operations, in which extreme accuracy may not be important as nominal variations can be taken care of in subsequent operations automatically and without additional cost. Obviously it would not pay to gauge every piece of such a product at these roughing operation stages, yet nominal gauging would be necessary. Thus it would be worked out at just what stages of manufacture it would be necessary to gauge work, and just what dimensions or points would be given attention.

There is an opportunity here for ability to be capitalized. The gauging should be such as to confirm every necessary measurement and condition, yet not one instance should exist one gauging operation overlapping another. It is also determined whether or not every piece will be gauged. The method of trucking, routing, and handling the product would be carefully considered, and the place where all gauging operations would be done and how they should be handled would be decided upon. In cases of gauging preliminary operations, that are not finish operations, it may be just as satisfactory and much more economical to gauge the material on a bench or table in the shop while it is enroute from one machine operation to another. Then again, shop layout character of the product, or peculiarity of the gauging or inspection operations, might be such as to cause this method to be impracticable or to be expensive. When such is the case an inspection room must be provided where the work can be accomplished to best advantage.

After the number of gaugings and inspections have been decided upon, the detail drawing would be consulted and the gauges or inspection apparatus would be designed. The manufacture of the gauges presents another problem. There are three distinct kinds or types of gauges to be made from every design it is desired to use. These are the reference or master gauges, inspection gauges, and shop gauges. The reference gauges are made with the greatest care and are provided with a very secure cabinet located in a room, free from dust, vibration and sudden changes in temperature. In fact such gauges should be kept between temperatures limited by two points not far apart from one another, the year around. These gauges should be designed to test all parts and to check as accurately as is humanly possible all measurements up to the limiting dimensions permitted in the design. These gauges are not used directly on the work except on rare occasions, but are kept to check the accuracy of the other gauges. The inspection

department usually is entrusted with the custody of them. In their design, adjustable features may or may not be featured. Should they be adjustable, the adjusting parts should be very effectively sealed to insure against careless or malicious tampering. Not all of these gauges, however, can be used directly on work, as they sometimes vary from the design of the inspection or shop variety by possessing certain extra flanges, or other sections, that prevent actual application to the work. Such gauges thus, can be used only for reference purposes. In addition to what might be considered a complete set of gauges for inspection or shop work, there appear in reference sets certain standards, such as plugs, internal thread gauges, thread plug gauges, etc., etc., which are useful for reference purposes only.

The inspection gauges usually are provided with tolerances slightly less than those permissible on the blue prints and those in the reference or master gauges. They are, however, quite capable of being applied to work and possess all the necessary qualifications for adjustments to compensate for wear. These gauges are used by the inspection department for the actual testing of work. The shop gauges have again a slightly smaller range between limiting dimensions than the inspection gauges. They are used by the production workmen to check their work as it comes from the machines.

Records Kept by Inspection Department

Every workman operating a machine should possess all the shop gauges necessary to test the work done on his machine. Work brought to his machine must have passed inspection in as far as the operations up to the present one, were concerned. Some record is, of course, kept of the work in progress, and whether the method of trucking is by elevating truck and special platforms, or other means, each lot is numbered and a record of its progress, rejections and rectifications must be kept by the inspection department. These records check up piece work records if such a system of remuneration is employed. Furthermore it produces an accurate record not only of each man, but of each machine, of each operation. It only takes a little additional clerical work to compile such records which are of inestimable value in picking out the most consistent producers, the machines that do the work without a shut down day after day, and finally it shows where a shop may be unbalanced. Further than that by recording the causes of rejections and reasons for rectifications it will be seen where the weak link in the method of manufacturing is located. There is a very wide scope for deduction here and the extent to which an intersection department is instructed to operate is only limited by the peculiar manufacturing problems of the shop which is being considered. Of course if the information obtained does not effect a saving greater than the cost of obtaining it, why it is poor business and should not be continued.

After it has been definitely determined to what extent records of machining operations should be kept, it should be determined how often reports should be submitted to executives, and also it should be seen that every executive interested in any of the features tabulated should receive a copy of each feature in which he is interested. Because it is a long way to the deduction that no matter how complete the records are, if they are not placed in the hands of the proper officers, they are next to useless.

Inspection of Foundry Work

Up to the present no mention has been made of inspection methods in connection with foundries. Supplies have to be checked in much the same way as machine shop supplies in-as-far as quantity is concerned. To check quality, chemical analyses have often to be resorted to. Pig iron, for instance, is always sold on analysis. Foundry facings, core binders, cupola washes, mounding sands, coke, etc., are usually sold with more or less rigid guarantees of certain analyses. Other products are marketed under trade names and the analysis is not generally known. But the old adage that says, "the proof of the pudding is the eating," is often true in the case of foundry work. If the castings are good and the cost within reason, not much criticism is offered. It is often assumed that if a very small percentage of castings is lost, it is better to leave "well enough alone" rather than attempt to introduce cheaper materials and methods at the risk of increasing the number of lost castings. Moulding appears to be a trade dealing with abstract things, and the moulders are sometimes temperamental. Thus no elaborate inspection methods are generally accepted and each foundry works out its own problems.

On the other hand a foundry is sometimes found where an intelligent supervision by qualified inspectors has worked out some remarkable results. No foundry can afford to let such matters drift. If machines are used, a record of the quantity and quality of the work done, should be kept. The results obtained from this core binder, this iron, and that facing, are very valuable to various executives and departments. The records of production of various men should be kept.

The inspection of castings is usually done by simply looking them over. If they look good they are assumed to be good. If defects turn up in machining the process is simply to scrap them. If a large number of castings, having the same defect appears, the reason is sought and conditions are changed with the idea in view of eliminating the cause of the effect. Probably in no other department of a metal working industry is it harder to suggest inspection methods of a general nature more than a foundry. The reason is that practices vary greatly and the methods of employing inspectors must be added to the conditions.

Final Inspections

After the various component parts have all passed inspection and these parts eventually find their way to the assembling department, the inspection department temporarily ignored. If parts refuse to go together, if machines refuse to function, then is the opportunity of the shop to "get back at", and tell the inspection department how useless they are. The inspectors have been "upper dogs" all along, but woe to them when the day of assembling occurs, becaues if things do not go right then it becomes a "day of reckoning." On the other hand if the machines do assemble easily, and function properly on tests, why they proceed to the paint room. Here all bright or finished parts are covered with some kind of a preventative for rust. Other parts are painted, stripped, etc. Then comes the packing, crating and shipping. Just where the authority of the inspection department ends, is largely a question of shop practice. In any event such supervision as is required in these connections is not of the highly skilled variety. Articles have to be substantially crated, and if for overseas shipment, exceptionally well so. Delicate parts should not be exposed to risk of damage, and many other self evident conditions of risk should be eliminated.

Scientific Apparatus

Discoveries in the field of science have been responsible for many scientific principles being applied to practical use for gauging purposes. Even a well informed engineer or mechanic is often surprised to learn of some peculiar application of a newly discovered scientific fact to the field of inspection. The thermo-electric couple, with the recording thermometers and pyrometers are great aids to the work of checking certain factors in a product. All recording instruments have a useful field. The sclerscope and the Brinnel methods of testing the hardness of steel are two examples of the more or less indirect application of certain principles applied to inspection purposes. To cover the field would be impossible, as usually each application is made only after a careful and exhaustive series of experiments have been made.

Organization of an Inspection Department

There is no hard or fast method of organizating an inspection department. Local conditions as well as the main organization of the factory, are often reflected in the smaller sub-organization. The chief inspector should have a first-class assistant. In each department he should have a foreman inspector. Each foreman should have under him, enough men to gauge the work as fast as it is produced, and to keep the necessary records. Should the department be large, it might be in order to appoint sub-foremen. The foreman's duties would be largely to supervise, see that gauges were properly used and were frequently checked, that records were properly and accurately kept, that production was not held up, that bad work was immediately reported, and the risk of spoiling work removed by having the machine produc-

Choice of Fixtures for Industrial Lighting

Type of Reflector Depends on the Work—Softening Shadows and Eliminating Glare—Keep Globes and Lamps Free From Dirt—Good Light Prevents Accident

By JOHN T. SCOTT

HAVING treated of the fundamentals of illumination design, we shall now consider the choice of reflectors and equipment in order that the best results may be had from our planning.

In the choice of reflector fittings for service, consideration is given to the class of work to be done, the area to be illuminated, location of operatives and machines, ceiling height, etc., as outlined in last week's Canadian Machinery. For general lighting, the type of metal reflector now generally used to obtain uniform results is the RLM standard dome, (abbreviation for reflector and lamp manufacturer standard), illustrated by Fig. 1. These reflectors are made under a standard set of specifications drawn up by the engineers of the principal metal reflector and lamp manufacturers, to obtain the best possible service from metal dome reflectors with gas-filled incandescent lamps.

Eliminating Glare

The use of the RLM metal dome reflector with the bowl-enameled or bowl-frosted lamp is desirable for a wide variety of industrial locations. This combination gives a direct lighting of full illumination value, but with softened shadows and freedom from glare, and is the type of lighting particularly recommended for machine shops and locations where reflection from polished metals is prevalent. The same care should be given to the choice of equipment for local lighting of machines or particular operations. Don't forget that the lamp filament should be concealed at ordinary angles of vision from the worker and other occupants of the shop. Also diffuse the light so that it does not reflect from the metal working parts.

Wherever possible avoid local lighting—in many instances it can be dispensed with. This can be made easier by the advantage gained from the development of a more efficient overhead lighting system. Even when local lighting is necessary, a high level of general illumination relieves contrast between the brightly lighted work and the remainder of the room, besides proving restful to the operatives' eyes. Care should be exercised in choosing the size of reflector equipment and to get it suitable to the size of lamp selected. Larger or smaller diameter reflectors will give poorer light distribution, and for the smaller size will reveal the lamp with annoying brightness.

Lamps And Voltage

Under-voltage burning of lamps from any cause results in a decrease in wattage, and therefore a decrease in current bills, but since this decrease in wattage is accompanied by twice as great a decrease in illumination, it really results in a net loss. In instances where a considerable increase in lighting intensity has been made or may be under consideration, it is important to investigate the amount of voltage drop caused by the increased load. The voltage delivered at the service switch may be up to standard, but if the circuits are overloaded, poor illumination and decreased wattage will result. In any instance where the desire to cheapen the wiring installation has resulted in the installation of insufficient copper, the voltage drop will be excessive, the illumination will be decreased, and the lamp efficiency impaired.

It is oftentimes found that people who do not fully appreciate all the resultant effects, are purposely using lamps whose rated voltage is higher than the circuit voltage, for the purpose of thereby increasing the life of the lamps. In practically no cases is such a practice justifiable, for the cost of the current consumed by a lamp is so much greater than the cost of the lamp that it is not economical to sacrifice even as small part of the efficiency of the lamp for the sake of even a considerable decrease in the renewal cost.

To purchase light efficiency, obtain lamps of known quality and of correct circuit voltage. Lamps have an average life of 1,000 hours and will maintain their luminous efficiency for that period with but very little variation.

Effect of Cleaning

Here is a single statement that would save hundreds of dollars if it was generally known. The loss of illumination due to the coating of lamps and reflectors with dirt may result in a loss of light equal to 60 per cent. or more before attention is given to the fact that they need cleaning. Think of what this

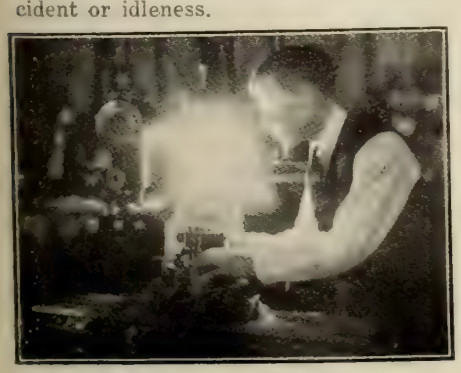
Author is engineer in charge of standardization work at the Sunbeam Lamp Works.

Example of well illuminated machine shop.

means in current consumption, loss of production, waste of materials, and risk of accidents. And then realize that the saving can be made by a simple plan of cleanliness; a periodic cleaning of lamps and reflectors with just soap and water. Shop cleanliness is a matter of routine—extend it to the lighting units.

It is surprising to see the way in which lamp units are neglected, and new and large lamps sometimes put into sockets where the only trouble was need for clean water. This is where use of

Bowl Enameled Mazda lamp.



the foot-candle meter to check up lighting values is going to repay its cost.

Finally, we must consider the question of shadows. For satisfactory lighting there must be no sharp black shadows to confuse the vision. Shadows are usually present when the illumination is not uniform. It would need expensive equipment to eliminate shadows entirely, but it is not even necessary as a certain amount of softened shadow is necessary for easy defination of objects. A model of illumination in this respect and one which will be fully appreciated is shown in the illustration accompanying this article.

Summarizing

Unfortunately a lot of indifference has to be overcome to make plain the fact that lighting plays an important part in modern industrial plants. There are still in use many Topsy Systems that have "just growed." Faulty and insufficient lighting costs in the end far more than efficient illumination. Poor lighting reduces production and increases shrinkage—a loss of time and money.

An increase of four times the lighting intensity will equal a sum that is but a fractional percentage of the pay-roll, and the sum spent will be well repaid by measurable increase in production. More attention to illumination is only a matter of the possibilities of its service to industry being seen by responsible executives. Lighting has power to stimulate and where adequately used there is little chance for error, accident or idleness.

Poor Method of Local Lighting

INSPECTION METHODS THAT HAVE PROVED SUCCESSFUL

(Continued from page 19)

ing the bad work held up until repairs are made. These are just general suggestions, but a successful foreman will see a multitude of ways in which he can act for the benefit of increased production of first class goods.

The chief inspector would work with his foremen and assist them in many ways. He would get daily reports from all foremen and would probably look over these reports. Under him he would have a staff which would finally compile all records and place them in the hands of the proper executives.

A chief inspector would have to familiarize himself with many engineering problems and would find it necessary to watch and study closely the problems that faced the firm with whom he was working. In times of high production he has a delicate duty to perform in keeping up both the quality and quantity. The production department will quickly bring up the quantity but it is up to the inspection department to bring up the quality. It is in these cases that a little friction occurs. A great deal of tact is sometimes necessary and it must be clearly understood than an inspector, although he may be first class in all respects, except in tactfuness, can never be a success without it. Thus a really big man, can fill the position of chief inspector and find scope for all his talents. In fact he can be a "power" in his organization. Mechanical skill is not by any means a useless factor in an inspector. The opportunity presented, of studying general shop manufacturing methods is valuable, and occasions are frequently found where both the man and the factory are benefited by the mechanical knowledge of an inspector applied in a practical way.

The field of an inspection department varies a great deal in different manufacturing establishments. Thus to treat the subject in detail a close study of the product, the method of production, the volume of production, the shop layout, the possibility of frequent changes in design, and many other factors would have to be made.

Piece Work and Bonus Systems

Shops that employ the piece work or bonus system, or in fact any system that rewards a worker more or less directly according to the amount of work he produces are sometimes uncertain of the quality of the product. This difficulty is easily overcome if a close inspection of the product is made, and a man only credited with the pieces that pass inspection. In some cases on record, workmen have operated machines where they not only lost their remuneration on a piece that was spoiled, but in addition were subject to a nominal fine. This is somewhat unusual, and only extraordinary conditions would appear to justify such a practice. The method of closely checking a man's production and only giving remuneration for good work, really assists the inspection department. Production workers will then keep their gauges, machines, and tools in good shape and will be interested in turning out good work only. When indications are such that would lead the worker to believe his machine needed adjustment or repairs, he would report such a condition immediately, learning that "a stitch in time saves nine." He also is directly interested in seeing that his machine is quickly returned to service so that he can again produce.

If an inspection department keeps the spoiled material down to a minimum, does not delay progress of work through the shop, and if assembling and preliminary tests show that the work has been conscientiously carried out, it is an assured fact that the money invested in their salaries and equipment has been saved many times, in a direct or indirect manner. The information that is tabulated, from data obtained by the department, often enables executives to obtain better administration. In fact many policies of the directors have been changed, and new ones formed from studying various forms of inspection reports and making commonplace deductions. The inspection department is with us permanently as in our modern manufacturing shops they have become indispensable. The various functionings of such a department present a very interesting problem to many executives, and the field of usefulness of inspection is ever broadening, and seems to be limited only by the resourcefulness of the executives themselves.

CANADIAN NICKEL REFINED AT HOME

A better era is promised for the Canadian nickel industry. J. L. Agnew, president of the International Nickel Co., of Canada is reported as saying that:—"Remodelling of the exploitation department is the salient feature of the development of the regime under its reorganization. Experts of high standing have been engaged with a view to broadening the field for nickel and monel metal parts. In the past most of the nickel has gone into armament and war material, and with the disarmament conference over and disarmament a fact because of the agreement to reduce ships and armament, there will be a substantial reduction of nickel for these purposes. The industry is therefore facing an entirely new condition, where new uses will have to be forthcoming to make the industry a success.

"In the meantime, the Canadian end has assumed tremendous importance. The production of ore and matte is entirely in Canada, and hereafter all refinement of nickel will be done at Port Colborne, the company having some time ago announced the closing of the Bayonne works."

Taking the *"Please Remit"* Out of Collections

Sample Collection Letters Which Have Proved Successful—Humorous Style Not in Favor—Each Debtor Should be Dealt With According to Character and Nature of Business

WHAT style of collection letter can I use to obtain the best results? Is there such a thing as a standard collection letter containing enough fundamentals to apply to all manufacturing lines? These, and other questions of similar character are bound to arise whenever bad debts are encountered, and it is the collection manager who is able to send forth the proper type of appeal who can afford to smile as he sees the cheques coming in.

A short time ago, Canadian Machinery wrote to several well-known firms in diversified lines, asking for their opinion as to what constituted a first class collection letter, and while opinions varied in some respects, one point was firmly established, viz., that a standard form equally applicable to all lines of manufacturing was practically impossible.

A considerable number replied to the effect that they had absolutely no trouble in collecting accounts, while others again did not believe in letters, but sent someone to collect the money. In the April 6 issue, Mr. Quigley, collection manager for the Ontario Wind Pump and Engine Co., Toronto, gave his ideas regarding collection letters in general, and in the material to follow we shall present several other opinions, allowing each one to speak for himself.

G. F. Morris, sales manager of the time recorder division of the International Business Machines Co., Toronto, has given us a sample letter which they have found to be successful in bringing in the money. He remarks as follows: "Naturally we all recognize that the proper type of collection letter is extremely hard to standardize and must be worded to suit the necessities of the case. There is plenty of room for improvement in the practice of compiling such letters and we need hardly say that we are always willing to copy the successful collector and trust that the discussion you have started will produce some good material."

Leslie S. Hall, vice-president of the Williams Tool Corporation, says that the subject of collections is entirely foreign to their company, as they never have to chase up collections, business being principally with dealers who paid regularly. "Last year at our American plant," continues Mr. Hall, "we only had $131 bad debts, while at the Canadian factory, we had $37, so you see we have very little need to study the problem of collections."

Here is how W. E. Hensman, credit manager for Crane Ltd., Montreal, sums up the situation. "We appreciate your invitation regarding the presentation of our views on the proper type of collection letter, but regret to advise that, although we have read innumerable so-called 'go-getters,' we have not yet come across one that we considered presented the proper businesslike attitude. We do not consider that a humorous letter would maintain good relationships with a real business man. We admit that it might be used once to a particular individual with good results, but cannot understand how any man giving the proper attention to his business will care to do business with a house publishing humorous letters. Our practice is to first of all send out a statement with an overdue account accompanied by a short letter pointing out the overdue amount and, after that, to deal with each customer in a way that we feel suits that particular individual. Of course, we do not contend that ours is the only method, but are yet to be convinced that a special letter, or series of letters, will answer the purposes of the credit department of all kinds of trades or houses. To be concise, we feel our views are best expressed in the old saying—'One man's meat is another man's poison'."

P. Ford-Smith, president and manager of the Ford-Smith Machine Co., Hamilton, says that he does not believe in any cut and dried form of collection letter, nor does his firm use any. He feels a humorous letter is entirely out of place, and summing up the situation, here is what he says:

"The way we look at collections, and we may say that we have had practically no trouble in the whole of our business experience of any moment, is this. We sell our goods on certain terms, and when the account is due we expect to receive our money, and we make our financial plans accordingly. If an account is not paid within a reasonable time of the due date, we take up the matter firmly by letter and insist on payment At times we have had to call on people, and this has generally been successful. On the other hand, we pay our own accounts on a certain system without fail."

L. L. Wildman, collection manager for the S. F. Bowser Co., says that the important thing is to know the customer's character, sensitiveness, or other attributes. The letter which is shown in this article is not meant so much as an actual letter which would be sent from their office, as it is meant to portray the particular points they have found arouse results, in other words, something that will create interest, and appeal particularly to the debtor's mode of life and business.

Should any other manufacturer feel he has a collection letter which contains a stronger appeal than the two shown, send it along, and we will be only too glad to publish it.

Mr. John Smith,
Toronto, Ont.

Dear Sir:—

This is a collection letter but not the kind of a collection letter that says "Please remit," and leaves ill-feeling behind it.

We have learned from experience that 90 per cent. of all trouble starts with a misunderstanding. If we can correct this, there is no trouble at all.

You owe us $32.38 covering our invoice of Dec. 30, 1921.

You know that you owe us for the above mentioned invoice, and that you have not paid us promptly, but we don't know why, so we are taking this opportunity of asking you what is wrong. If there is a possibility of a misunderstanding on our part why just merely put it right up to us. We will come more than half way for you any time, but you surely do owe it to yourselves and to us to explain.

If there is nothing wrong, then you owe it to yourself and to us to pay up your indebtedness according to the terms as per the invoice. This is just good sense and square business, now isn't it?

Yours very truly,

This style of letter has brought good results for the International Business Machines Co.

The American Society of Steel Treating are holding a sectional meeting in Pittsburg on May 26, when a number of interesting papers will be presented.

Mr. John Doe,
Somewhere, Ont.

Re "Dusty Roads" vs. "Green Pastures"

Dear Sir:--

"Dusty Roads" controls an active business. Shrewd managership rewards him with a liberal profit. His business should be a source of enjoyment, but—it is not. A keen business insight leads him to invest profits until he cannot meet his bills. His mail is heavy with harassing creditor's letters demanding payment of overdue bills. Considerable time is spent explaining and promising.

"Green Pastures" also controls an active business—enjoys liberal profits and gets the best out of life. Why? He discounts his bills, meaning an addition to his profits. Creditors never trouble him; they seek his patronage. His time is spent solely in planning and developing his business.

Only a few hundred dollars represents the difference between "Dusty Roads" and "Green Pastures"—only a few hundred dollars stands between discontent and happiness.

Many businesses are reflected in our accounts, and often the writer thinks of "Dusty Roads" and "Green Pastures." Imaginary—yes; yet just slightly exaggerated types of people we meet every day.

Your account, Mr. Doe, has just been brought to my attention. You are again in arrears to the amount of $228.00. So many times has this same situation arisen, that I am wondering if you are not overlooking a good bet; whether you are actually getting all of the enjoyment out of life and business that you should. Why not make a little extraordinary effort and arrange to pay up all overdue accounts and start discounting your bills. Ten to one you would never get delinquent again. Better try it.

Anyway, let us have a remittance, as it is imperative that this account be brought up to date before the 20th instant.

Yours very truly,

This letter is designed to arouse interest, and appeal to the debtor's mode of life and business.

Consider Amount of Spoiled Work

Poster by Fred. G. Kent, Supt., Lodge & Shipley Machine Tool Co., Cincinnati, Ohio.

STOP a minute and consider spoiled work. If every man in this shop will appreciate fully what it means, the amount can be cut 90 per cent.

There is, first, the direct loss, which includes the cost of the material and the labor which has been spent upon it. There may be a small scrap value, but otherwise what is lost can never be recovered. But the direct loss is only a beginning. There are other greater losses. Spoiled pieces must be replaced, usually in a small quantity lot. It costs from three to ten times as much per piece to make ten pieces in a lot as it does to make a hundred; sometimes the ratio is even greater. Also remember that rush jobs are always more expensive than regular jobs, and replacement of spoiled work is always a rush job.

While this small quantity job is being done, there might be made, instead of it, some other job which is crowded out of its place in the schedule by the spoiled work. The upsetting of the manufacturing schedule is the hardest thing to put an exact value upon, but is the greatest loss that we have, due to spoiled work.

Remember that raw material not only costs money, but is often very hard to get. Every time the foundry runs on a short lot of a few pieces to replace spoiled work, it is taking time that would produce much needed material for regular work. It is also taking the time of the purchasing department in getting the order for this replacement material pushed ahead of the older orders already placed. Sometimes it is almost impossible to get the replacement material at all, and by the time it is obtained, the work for which it is needed has been delayed beyond the possibility of any approach to efficient production. In certain cases, such delay has caused a loss through penalty, which has more than wiped out any profit on the order. Also, where there are no penalties involved, the shortage on the erection floor will put off the shipment of some given machine at a time when there is nothing else that can be substituted for it on the shipment schedule. This is a loss that can never be made up. Work that is imperfectly done, so that it must be done over or patched up, may save the direct loss of the material, but the delay due to time spent on it is just as serious and expensive as in the case of spoiled work.

Careful observation of three small rules will help greatly:

First—Make sure that the first piece in every set-up is passed by the inspector before doing any further work on the job. This is a simple rule, and must be obeyed.

Second—If a blueprint is smudged so that you cannot be sure of the figures, or if you are in doubt as to the meaning, put it up to the foreman. Don't guess. Better lose time making sure than spoil the work. Don't use an indistinct blueprint; insist on a fresh one.

Third—Don't use a jig or tool that you think is in bad shape, put it up to the foreman. Don't use any jig before you are sure you understand how.

Cutting down spoiled work will save money, increase the production, cheapen the cost and raise wages.

PALM OIL AS A FUEL

Palm oil is reported to have given successful results as fuel for a stationary two-cycle semi-Diesel engine of Swedish make, the tests having been made in Belgium. The engine's storage tank for the oil was divided into three compartments, and so fitted that the hot exhaust gases and the cooling water from the cylinder melted the contents of the tank. The wire screening dividing the tank served to filter the melted oil. The engine was started with crude petroleum, and as it warmed up the change to palm oil was made through the automatic feed.

OVERHEATING IN FACTORIES

The commonest evil in air conditioning in factories, is the slight but highly objectionable overheating which obtains in any ordinary window-ventilated workrooms where there is no marked overcrowding and no special process tending to overheat or vitiate the air. This evil can commonly be controlled by watching the thermometer, by common sense regulation of the artificial heat supply and the use of windows before and during the shift. Heat hazards of high degree, says the U. S. Public Health Service, can not be summed up so simply. In cool weather, says this report, they can be adequately controlled by properly designed and operated systems of fan ventilation; but in summer time, although they can be mitigated by ventilating systems that produce vigorous air movement, they cannot be fully controlled except at prohibitive expense and must therefore, in general, be accepted as an unavoidable incident, of the employment. The effects, however, may be minimized by short spells of work alternating with rest periods.

When You Close the Plant at Night—Is It Safe?

Showing the Dangers Existing in the Oil Room of Many Factories—Points to Guard Against and How to Eliminate the Danger —Proper Storage of Oils Very Essential

IN CONSIDERING the dangers attendant upon the storage and handling of oils, we are apt to think only of gasoline and naphtha. This is a great mistake, as every oil carries with it a menace to life and property and its handling should be safeguarded in every possible manner. Until this fact is universally recognized and all oils are handled in fire-proof, evaporation-proof steel tanks, we must expect to pay an enormous fire loss due to the careless handling of these products. It is true that the danger of handling gasoline is greater than in handling other oils. This is so well known, however, that familiarity with it in many cases induced carelessness, so that it is well that we consider the treacherous nature of this product that we may always be on our guard.

Gasoline, unlike the other heavier petroleum products, throws off an explosive vapor constantly, even at extremely low temperatures. Five gallons will generate 8,000 cubic feet of gas, which, when ignited, expands to 4,000 times this space. The explosive force of one gallon of gasoline properly mixed with air and compressed is equal to 83 2-3 pounds of dynamite or fourteen times greater than dynamite. This means that if you have 100 gallons of gasoline on hand, you are storing the equivalent in explosive force to 8366 pounds of dynamite. Gasoline is, in fact, more dangerous than dynamite and there is more liability of an explosion. Dynamite will only explode from two or three causes which may be easily guarded against and which must occur in its immediate vicinity.

Safeguard Your Interest

The vapor from gasoline is heavier than air. It settles to the floor and runs along the floor much as a stream of water would only that it is an invisible stream. This vapor will settle and remain in a depression in the floor or under the floor for days and even weeks, unless disturbed by a circulation of air, until a spark causes the accumulated vapor to explode. This spark does not necessarily have to come from a lighted fire, but may occur through a person striking a nail in their shoe on a nail in the floor or other similar unavoidable causes. The records show that under certain atmospheric conditions, spontaneous combustion will occur in this accumulated vapor. A case is on record in which the gasoline fumes were carried out of the building to a lighted lamp thirty feet away from the building, taking fire and flashing back to the building, which was entirely consumed. If you are handling gasoline in any way but the right way, you are in just this position and you can never foresee when the blow will fall.

It is past understanding, in view of these facts, that many concerns with their entire capital invested in the business, will give so little thought to safeguarding their interests. With the factory, shop, mill, or mine heated, they will at night lock up this explosive in a warehouse or building adjacent to or connected with the main plant. After locking up fire and this explosive vapor together, they will, in effect, wager their entire investment against the merely nominal expense of fire-proof storage that this vapor and this fire will not get together.

Kerosene is not as dangerous as gasoline, yet at a temperature of 70 degrees F. or over, it throws off an explosive vapor. At a higher temperature in which there is an open tank of kerosene, there should be kept up a circulation of air equal to 200 cubic feet per minute for each gallon of the exposed oil. These figures vary, of course, with the volatility of the oil and temperature of the air and oil. Such a circulation of air is not practical in the usual manufacturing establishment. Hence the necessity is apparent for evaporation-proof, scientifically correct storage for kerosene as well as for gasoline.

Watch the Refuse

All petroleum products, including lubricating oils, produce the explosive vapor. The danger from lubricating oils, however, is chiefly from spontaneous combustion where waste, sawdust or shavings are used to absorb the oils spilled on the floors. Many fires in factories and oil rooms have been traced directly to this cause, as it is a very common practice to neglect the accumulated refuse, which in time, bursts into flames.

The gravest danger that confronts the consumer of oils aside from the gasoline danger is, however, from the paint oils, such as linseed oil and turpentine. A piece of cotton waste saturated lightly with equal parts of linseed oil and turpentine will, if left in a closed room, such as an oil house or stoveroom for the night, burn from spontaneous combustion in three hours' time. Instances are not even lacking of fires being started in this manner when the waste or oil-soaked cloth was left in the open air. Two years ago a fire occurred in Minneapolis from a cloth which had been used in oiling a floor and was left on the porch. North Dakota has, in the past year, suffered a loss running into hundreds of thousands of dollars from fires started by spontaneous combustion in oil houses. This property loss is appalling, but who can estimate the value of lives sacrificed annually to the mistaken policy of "economy" in equipping an oil room?

We are living in an age of increasing danger to life and property from many causes unknown to our fathers. Developments of modern inventions in all lines such as electricity, automobiles, etc,. each brings its corresponding increase in danger to life and property. These advances in the development of our civilization bring a responsibility that we cannot ignore. The merchants and the factories to-day are compelled to meet the conditions. For instance, they are compelled to store large quantities of various dangerous oils. Happily, we are, also, in an age when master minds have set themselves to the problem of minimizing all such dangers. The storage

(Continued on page 27)

A plant using this method of reclaiming oil will find an immense saving every year.

Features of Maag Type of Tooth Profile

No Undercutting of Pinion Teeth—Slip Practically Eliminated—Less Breaking Leverage and Greater Strength—Rack Shaped Cutter With Straight Tooth Profile

IN order to procure a gear tooth profile which would be an improvement on the present standard involute system, Max Maag of Zurich, Switzerland, after extensive experiments, has developed the gear tooth profile which bears his name. The new form of gear tooth does not tend to become undercut in pinions having a small number of teeth. In fact this feature is so marked that pinions with as few teeth as five have been cut and placed in successful operation. These pinions run smoothly and the teeth are not undercut..

The tooth form is a true involute, from the points right down to the fillets at the roots of the teeth. In ordinary involute gears the profile is symmetrical about the pitch circle and is a true involute only down to the base circle, beyond which point the flanks are radial or even an optional form is permitted, provided that the pinions will run freely. The result is an unsatisfactory profile in pinions of few teeth, where the base circle is relatively larger than in gears with a greater number of teeth. In these pinions the diameter of the base circle closely approaches the diameter of the pitch circle. Thus the effective part of the tooth is the face, or that portion of the profile which lies on the outside of the pitch circle. This condition, coupled with an undercut tooth does not make it practical to use pinions with much less than fifteen teeth. Consider the case where an ordinary pair of involute gears are used, with a pinion of a small number of teeth, if the thickness of both the gear and pinion teeth at the pitch line are approximately half of the circular pitch, the gear tooth is perhaps fifty to one hundred per cent. stronger than the pinion tooth. In the new gear tooth the profile is symmetrical more as regards the base circle so that such a condition does not exist. By referring to Fig. 1 the two tooth profiles can be compared. It will be seen that the Maag gear is shorter and is much more rugged at the root.

Generating Maag Gears

Maag gears are generated by rolling the gear blank in a rack shaped cutter. Fig. 2 shows how this is accomplished. The cutter operates with a reciprocating motion in a vertical plane. Between each stroke the blank is revolved and moved forward a little as if it were rolling in a rack. Due to the well known fact, that involute racks have straight sides, the cutter is comparatively easy to make and to measure with absolute precision. In the finishing operation, each tooth in the gear being cut, is generated by the same two or three teeth in the rack cutter, so that uniform accuracy in the gear is obtained. The accurate rack shaped cutter is one of the outstanding advantages of the Maag system. It is much easier to produce than a curved cutter, which itself must be generated. Thus one source of inaccuracy is eliminated here. As only one cutter is required for each pitch, independent of the number of teeth in the gear, to produce theoretically correct profiles, only a small number of cutters are required to handle a wide range of gear problems.

Straight Sided Back Cutter

The difficulties of grinding and measuring correctly the curved surfaces on an ordinary cutter, are apparent. Fig. 3 shows three Maag cutters. The straight lines of the profile of the rack tooth cutter are ground after hardening.

Cuts and data through courtesy of Miles-Bement-Pond Co.

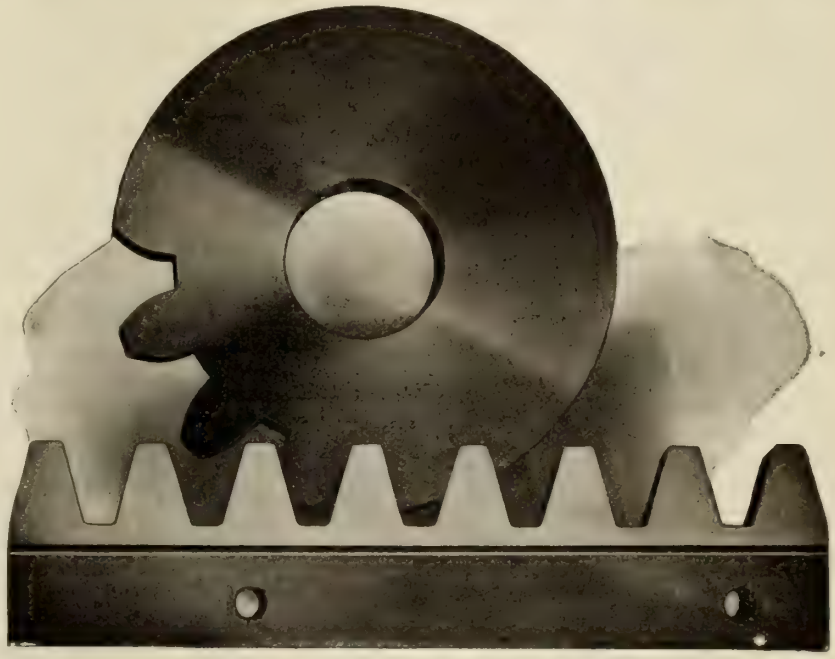


Fig. 2.—Maag gear being generated by a rack-shaped cutter.

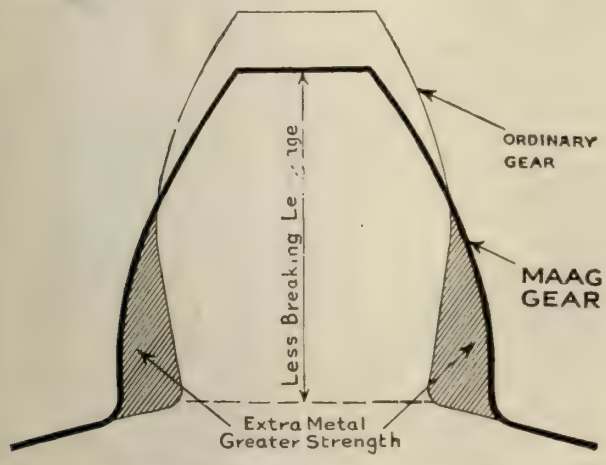

Fig. 1.—Maag gear profile superimposed on an ordinary gear profile.

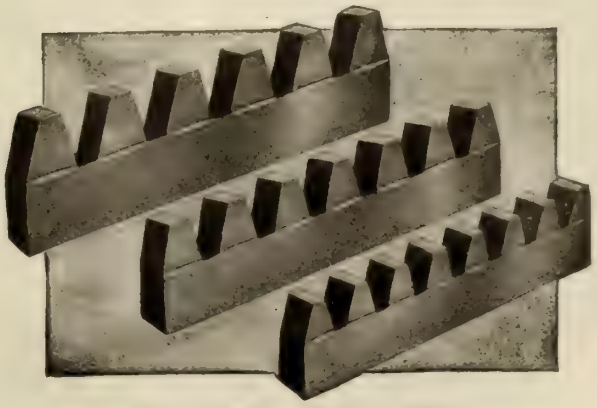

Fig. 5.—Maag rack shaped cutters.

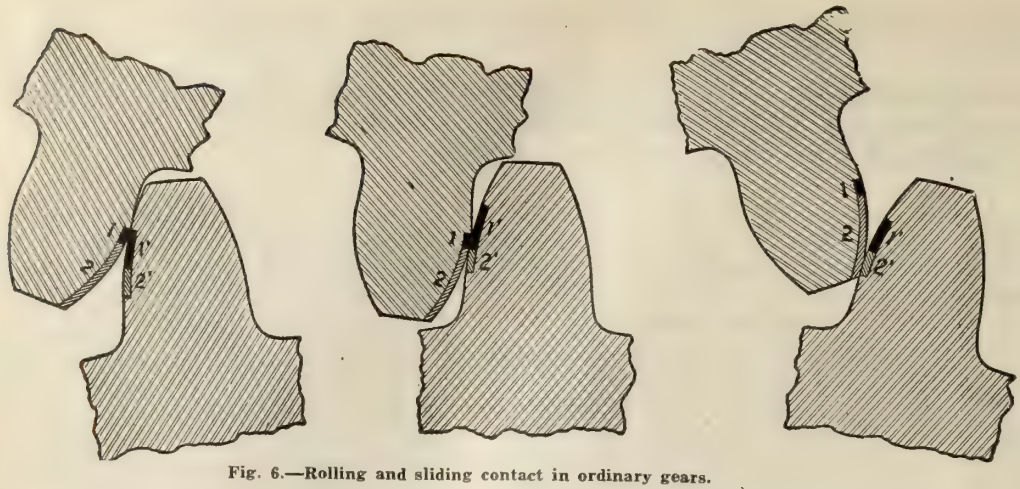

Fig. 6.—Rolling and sliding contact in ordinary gears.

Fig. 11.—Maag helical gears, 3 to 3.

Subsequent sharpening does not destroy the profile. The involute form of tooth that is generated by this form of cutter is smooth and theoretically correct.

The basic strength of the Maag form of tooth is shown graphically in Fig. 1. Both of the outlines shown are taken from 12 tooth pinions. At the base where the ordinary tooth is undercut the Maag tooth is widest. The difference in length is noticeable. The greater length of the ordinary tooth does not increase the working face of the tooth, but merely adds to the breaking levers on the base section. It is known among those who have studied gears carefully, that when teeth are stressed to their limit, they invariably break along the base line. Thus it is obvious that Maag gear design has strengthened the tooth at its weakest point.

Rolling vs. Sliding Motion

Rolling motion between gear teeth means quiet smooth operation. Sliding contact leads to friction, noise and wear. In the Maag gears, it is the rolling motion that is predominant. This is clearly illustrated in the Figs. 4 and 5. Fig. 4 shows two teeth of a standard drive, as frequently used in machine tools, cranes, etc., while Fig. 5 shows the same two teeth generated by the Maag method. In these diagrams the different parts of the tooth profiles which work together have been marked such as 1 and 1', 2 and 2', etc. If these portions were of equal length true rolling motion would be accomplished. The difference between the sections 1 and 1', 2 and 2' therefore represents the amount of sliding.

The Maag type of tooth more closely approaches the ideal condition. ratio of rolling to sliding contact in the Maag tooth, is nearly three times that in the ordinary type, which fact results in a reduction in noise and wear with a corresponding increase in life.

A further comparison of these diagrams shows other differences. In ordinary gears, the amount of tooth face that actually generates motion—the active profile—is only a portion of the whole profile. The rest is valueless as far as performing work is concerned. It will be seen that nearly the whole of the Maag tooth profile is active. This feature serves to better distribute the wear, giving long life to the gears. Grooves and ridges are not easily worn, and consequently the original tooth profile is preserved throughout the life of the gear with the quiet and smooth running features.

Uniform Speed Problem

The tooth outline of ordinary pinions having a small number of teeth, is modified to prevent interference. This modification of the true involute curve causes the pinion to drive with varying velocities, depending upon which part of the tooth is in contact. This varying velocity drive is one of the fundamental reasons for the noise and unsatisfactory service ordinary pinions give at high speeds. Maag gear teeth generated to the true involute form, drive with velocities practically uniform. Such advantages are extremely important in drives for paper machines, printing presses, and similar equipment where a varying velocity is extremely detrimental to the quality of the work produced.

In ordinary gear design, as the number of teeth in a pinion decreases, one of two expedients becomes necessary to avoid interference; either the teeth must be undercut, thus weakening them, or the involute curve must be altered, causing noise and rapid wear. To limit this faulty action, most engineers agree that 12 teeth is considered the limit, below which it is considered both unsafe and undesirable to go.

Strong-toothed Maag pinions can be produced wth 8 or 10 teeth, and in exceptional cases with even as few as five teeth. In accomplishing this, no sacrifice of those desirable features which distinguish the Maag gears with the larger number of teeth, is entailed. Thus this type of gear, offers to machine designers and gear users an increased freedom in the selection of gear drives, especially in regard to centre ditances, pitch, and number of teeth. Fig. 6 shows the comparison between the two types of gears, each with the smallest desirable number of teeth, as regards tooth strength.

Maag Spiral Gears

The Maag system of gears is reasonably flexible. It lends itself readily to the production of spiral gears. Practically any combination of numbers

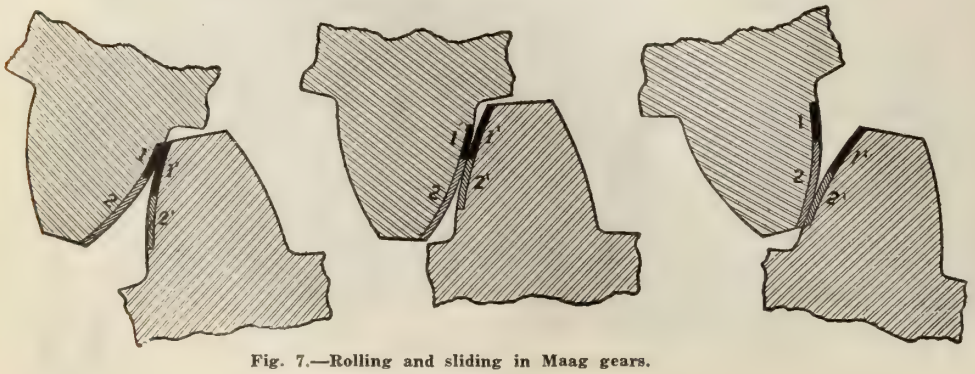

Fig. 7.—Rolling and sliding in Maag gears.

Fig. 12.—Maag spiral gears.

of teeth can be cut with standard cutters. The superior strength and other features of the Maag form of tooth are equally as advantageous in spiral as in spur gears. Maag spiral gears are used largely for timing gears and governor drives on internal combustion engines, on account of their accuracy. Fig. 7 shows a pair of Maag helical gears with a tooth ratio of three to three. Fig. 8 shows the valve shaft drive on an internal combustion engine, where Maag spiral gears are used.

Applied to Herringbone Gears

Maag herringbone and helical gears are planned and generated on the same type of machines and with the same cutters as spur gears. The ideal theoretical involute tooth profile is simply carried from the spur to the helical form. The most suitable gearing for a drive is selected, then these gears can be actually produced regardless of pitch or helical angle. Since any angle of helix can be cut without the necessity of special cutters, the angle that will produce an overlap of the teeth practically equal to the circular pitch (or the multiple of same) is determined and used in practically all cases. The resulting advantage is that with an even overlap, the length of engagement is always constant. This means that in Maag gears the load is always carried by the same total working length of teeth. In gears with an uneven overlap this is not the case. This uniform working length of teeth permits of quiet and smooth operation and also tends to add to the length of life of the gears.

The possibility of making correct pinions with a very low number of teeth, permits of designs that would be impossible with ordinary gears. Smaller centre distances can be often used to great advantage. Higher speed motors, in motor drives can be used, which often is a factor in materially reducing first costs of equipment.

WHEN YOU CLOSE THE PLANT AT NIGHT—IS IT SAFE?

(Continued from page 24)

and handling of oils has been reduced to an exact science, so that there are now available means of handling gasoline as safely as spring water.

Special equipment has, also, been designed for handling each and every oil in a manner best suited from the standpoint of economy, convenience and safety. The up-to-date merchant to-day is taking advantage of these appliances, so that we may in confidence look forward to a time when fires caused by careless handling of oils will be unknown. This will be brought about by various causes. The instinct of self-preservation is strong with everybody, and all must realize the risk in the careless handling of explosives. The fact that these safety appliances conserve the efficiency of the products, preserve the quantity intact and enable losses to be turned into profits brings enormous pressure to bear upon the thoughtful man. Public opinion, national and state safety boards, will soon demand that every man will, at least, cease to menace his neighbor's property and his neighbor's life by unnecessarily lax methods in the handling of dangerous explosives.

Proper Storage Essential

The increasing prices of all kinds of oil and general economic requirements demand the proper storage and distribution of these liquids. Millions of dollars are lost annually due to the deterioration of the quality and waste in handling improperly stored oils. Hot and cut bearings, prematurely worn machinery are very frequently due to deteriorated or contaminated oil. This enormous loss is usually never traced to the right source—poor oil storage. The same criticism can be made of improperly stored paint oils, varnishes, dryers, etc. Competition in practically all lines demands economical production—that means elimination of waste so far as possible in every department of the industry.

Your oils, etc., can be checked in as they are received and accurately recorded as they are used. You can keep just as accurate account of your oils as you can of your tools. All railroads, mines or manufacturing institutions maintain stockrooms for the purpose of receiving and distributing all of the supplies used by the institution. This is considered absolutely necessary in order to reduce losses and to maintain a cost system. Money is invested in oils just the same as any other supplies, yet it is a known fact that in most institutions no record is maintained as to the quantities received or dispensed. The purchasing, storing and the distributing of lubricating and paint oils, gasoline, naphtha and other similar liquids is just as much a science and a part of the shop cost system as any other department.

Industrial plants of all kinds, especially railroads, are experimenting continually to learn how the cost of lubricating can be reduced and methods improved, forgetting apparently to investigate the oil house of the storeroom where the oils are stored and issued, the place where the percentage of loss is usually the greatest. The installation of a modern storage system for oils, etc., need not necessarily imply the outlay of large sums. We have found this "big investment" idea on the part of men in charge of industrial institutions has frequently prevented them from considering the purchase of equipment. It is not always necessary, or even advisable, to put in at one time all the equipment the management might feel would be needed ultimately.

Modern storage equipment for handling liquids is really divided into two general types. One for handling volatile liquids, such as gasoline, naphthas, paint oils and varnishes and the other for handling non-volatile liquids such as lubricating oils.

The first of the two general types requires underground storage tanks for gasoline or naphtha and above-ground storage for the paint oils and varnishes. This arrangement usually meets with the demands of the various laws governing this type of storage. Where underground tanks are required they should be cylindrical in design. If made of galvanized steel all seams and rivets should be carefully made and then soldered inside and out. If heavy metal is used such as three-sixteenths steel or heavier weights as conditions or the capacity of the tank may make necessary, then all seams and rivets should be carefully caulked. Storage tanks for volatile liquids require special care in construction.

If above-ground tanks are essential these are made in rectangular shapes, the height and length remaining constant and the width varying according to capacity desired. This arrangement permits the addition of other individual units to the system and does not destroy the uniformity of the battery of storage equipment. Rectangular tanks are made with the same care as the cylindrical designs.

Specially designed pumps of either measuring or non-measuring type are connected by pipe lines to tanks buried underground or inserted in the top of tanks for above-ground use. Accurate dives are prov'ded on the measuring pumps for the delivery of desired quantities of liquid. Gear driven meters may be added for the purpose of checking consumption. Locks are supplied on both types of tanks and on the pumps as well. This prevents unauthorized usage and theft. Where a battery of individual units is used barrel track and barrel drainers are used in connection with small chain hoists. This makes it very easy to handle the barrels and drain them comp'etely into the manhole of the tanks. This saves labor, time and liquid and prevents the loss of liquid due to the return of liquid in barrels which have not been properly drained by the old style spigot method. Dirt, dust and sediment are kept from the liquids, fire danger is entirely eliminated, valuable storage space is saved, labor is lessened, cost and consumption are easily arrived at.

Adjusting Vocational Training To Local Needs

Large Sum Appropriated for Promotion of Technical Education —Great Impetus Given to Movement—Branches of Activity to Which Program is Being Adjusted

SPEAKING about technical education in "Canada as a field for British industries," a writer remarks as follows:—"Another question affecting labour in Canada is that of technical education. In 1910 the Canadian Government appointed a royal commission which spent two years investigating technical education in North America and Europe, and prepared a definite programme for the development of this work in Canada. Industrial training or technical education as outlined in the report of the commission has for its aims: (1) preservation of health and the vigour of life; (2) the formation of good habits; (3) the development of the sense of responsibility and duty; (4) the preparation of the body, mind and spirit for following some useful occupation; (5) the cultivation of the mental powers, the acquisition of knowledge and the development of the scientific spirit with direct reference to the occupation; (6) the promotion of goodwill and desire and ability to co-operate with others; (7) the maintenance of standards and ideals; (8) as all-inclusive and ultimate, the perfecting of the human spirit, the improvement of the quality of life itself and the betterment of the conditions of labour, leisure and living.

The war prevented immediate action on the recommendations of the commission, but in July 1919 the Government passed the Technical Education Act by which a total of $10,000,000 is to be granted to the provinces during a period of ten years for the purposes of promoting technical education. This assistance has given a decided impetus to the work and every province is now building new technical schools. The total number operating in the Dominion in 1920 was 139, with an aggregate enrolment of 60,546 students.

Variety of Courses

These schools conduct courses in every branch of industrial and commercial occupation. Pre vocational classes prepare juniors for apprenticeship or for regular vocational courses. Part-time co-operative or continuation classes provide special instruction for apprentices and juvenile employees. Evening unit courses are provided for skilled and unskilled workers in all branches of industry who wish to prepare themselves for promotion. Vocational and technical day classes prepare students for employment in industry and for entrance into advanced classes in technical and commercial colleges and universities. Special courses are provided for women and girls. Correspondence courses in mining are conducted in British Columbia, Alberta, and Nova Scotia

The major lines of activity to which the vocational or technical education programme is being adjusted are; (1) wholesale and retail business, including importing and exporting; (2) banking, brokerage, and insurance; (3) metal products-hardware, machines and tools, automobiles, heating and ventilating equipment, electrical equipment, farm implements and machinery, steam power equipment—stationary, marine and locomotive—and railroad equipment; (4) wood products—buildings, furniture, pulp and paper, farm equipment vehicles, and automobile bodies; (5) mining—coal, gold, silver, copper, and nickel; (6) railroad operation—apprentices, shopmen, trainmen, enginemen, telegraphers; (7) marine engineering and navigation; (8) stationary steam engineering and steam power plant operation; (9) hydro-electric plants—transmission of electrical energy for lighting, heating, street and interurban electric railway purposes; (10) home-making and wage earning occupations for girls and women; (11) the skilled and semi-skilled trades; (12) agriculture; (13) municipal, provincial and federal civil services.

Vocational schools are controlled by advisory committees of the municipal boards of education, consisting of representatives of the board, employers and employees. The courses of study are organized to meet the needs of each community—industrial, agricultural, or whatever they may be—and new courses are added as occasion demands. The point of most significance to the manufacturer is that the advisory committee co-operates with local industries in providing the most beneficial type of instruction to all classes of workers.

GRAPHITE AS A LUBRICANT

It is well known among lubrication experts, but not by the average run of mill and factory officials, that the consistency of any grease or oil has to be suitable to the weight and rapidity of motion of different machine parts, a lightly constructed machine, such as a watch, requiring a very thin oil to enable it to run. On the other hand, a thin oil proves to be unsatisfactory for roll and pinion necks, as it is squeezed out by their weight before it can get in efficient work. Suet and water mixture is like a thin oil, it being very costly in the end as regards the length of time that rolls can be operated before they are thrown away in the scrap heap. Graphite works on an entirely different principle from oil, and it is the best lubricant of all for heavy machinery in rolling mills. Metals are never smooth.

PRODUCING FIREBOX STAYS ON THE AUTOMATIC

Many manufacturers have taken advantage of the quiet industrial period to develop improvement in existing equipment. Without making any outstanding alterations in design the Alfred Herbert Co., have by slight modifications and general tuning up, succeeded in obtaining marked increase of output on their automatic copper stay machine. The revised machine has reduced the production time per stay from 70 seconds to 42 seconds, an increase of well over 50 per cent.

Can Welfare Work Be Carried To Excess?

Should Football and Baseball be Played in the Noon Hour?—Do Card Games Create Bad Feeling Among the Workers?—Actual Experience in One Plant by Shop Superintendent

"LEE BLANK & Sons have decided to purchase several baseball outfits for their men to use in the noon hour this year." I remarked to a superintendent of 18 years' standing and his reply is well worth recording. In fact, the best way, is to let him speak for himself.

"So I notice—oh well, they will soon find out the folly of the new move. You know, I don't want you to think from my seemingly sarcastic remark, that I do not favor the worker, for I do. I was one of the boys myself several years ago, and when in that position, felt that the superintendent was a hanged old grouch, who wanted to grab off all the glory for himself. No doubt quite a few feel the same way about me but however—

"To explain why I don't agree with the use of baseball outfits in the noon hour, I'll have to still further back to the time we first started this so-called welfare work. Right off the bat, let me put myself on record as favoring all welfare work that doesn't smack of paternalism.

"What started us off on the noon hour period was this. We had a few employees who were good workers, but men who felt the bosses were scoundrels who could own automobiles simply through the profits made by the workers. Note carefully that the superintendent was not included as a working man. Unfortunately these men were kept under cover pretty well, and used the noon hour for their soap box oratory. We discharged the worst of them, but the seed of discontent was there, in spite of the fact that we knew we were paying high wages, treating the men right, and keeping the factory in good shape for them to work in.

"After some thought we built a rest room, and some card tables, and it was surprising how the men took to it—at first. Like some old woman's tea party, they soon bunched off in cliques, and unfortunately bitter rivalry developed. One particular case is well worth mentioning. We had an old man working for us, who was crippled. In fact we kept him, more through kindness, than for his usefulness. Well, old Dad, as we called him, was always given a place at one of the card tables, and although he was always the last to arrive at the table, he was sure of his place—until one day, I hired a new man, who while a good worker, was inclined to be a bully. Of course, I didn't know that when I hired him.

The first noon hour, this man spied the empty chair at the end of the table and plumped himself down into it. Someone remarked that Dad would soon be coming along, but Mr. Newcomer stuck. In a few minutes along came Dad, the boys explained the unwritten law, but with no effect. Rather than lose their card game, they started to play with the new arrival and old Dad went into discard. In fact he's there yet. I heard about it, went to the new man, explained the circumstances, and he came back at me to the effect he had as much right as Dad to play, which, although so fish, was perfectly true.

"The next trouble we ran up against was that the men got so interested in their card games, that they ate their dinner before noon, in bitefuls, and once the whistle blew, there was a rush for the time cards, then the playing cards. Soon, the keen rivalry became almost fighting, and in fact, had it not been that I made it a point of dropping in occasionally, trouble might have developed.

"Luckily, or unluckily, spring came along, and the open fields called the boys outside. Someone brought a football, and we erected goal posts for them. In fact I used to play football in my earlier days, and one day decided to go out kick a few myself. I wasn't long in the game before along comes the card table trouble maker, who had now established a name for himself as a roughneck. He was a semi-professional footballer, and better than all the rest there. Someone passed the ball to me, he charged, I went down in a heap, and after I got up, I went over to him and said, 'Look here Joe, have a heart. This isn't a final game for the cup you're playing. Play easy.'

"This paper is not fireproof and therefore cannot record his answer, and had it not been that the move would have been put down to spite work, he would have been minus a job right then. However, I do not believe in holding a grudge and his work was satisfactory inside the plant, so he stayed on.

"My experience was duplicated many times by others, and before long, very few cared to go out on the football field with this man as he was so rough.

"Next came the baseball and without entering details, the same trouble occurred. In this case he wasn't the only rough one, and dirty tactics crept in. From this recital one might gather the impression we were a rough bunch, but such was not the case, previous to the sporting ? spirit.

"The lost time after the noon games was awful. The men got so that they paid little attention to the warning whistle, and would come running in on the last minute, punching their clock, and gasping for breath at the same time. Of course it took at least an hour before they could produce at anything like normal, and I had quite a time preventing them discussing at length the events of the noon hour.

"Since then, we have discouraged the freedom before allowed. The men still have their rest room, but if they play baseball, they MUST be in on time, and if they come in all heated up and exhausted they are told about it plainly. In other words, we were forced in no uncertain manner to put the men in their proper place. Who is to blame for this condition? Surely not the firm. They tried to give the men all the freedom possible, but a few spoiled it for everybody. This holds good for practically every factory. There are always a few who spoil it for the rest, by overdoing it, and until the end of the world we can expect this condition to remain.

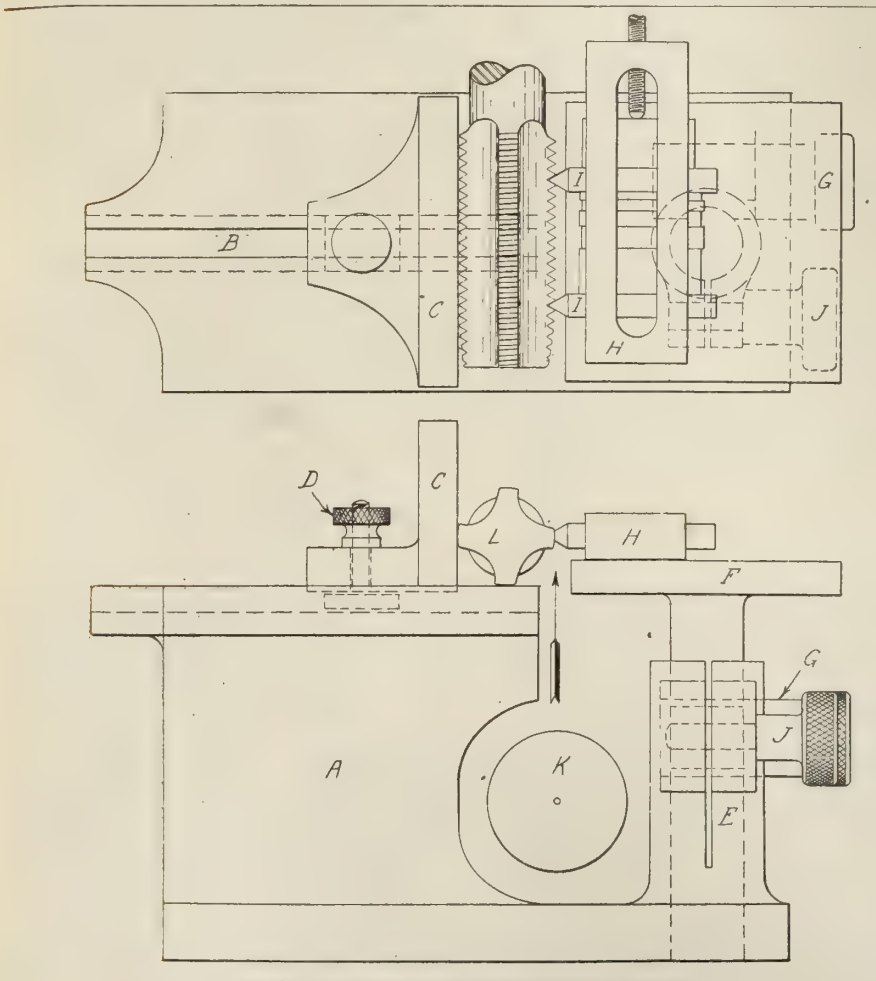
"We are not unfair to the workers, far from it, but they must toe the mark, thanks to themselves. Some say I am pretty strict, but none can say I am unfair. Mr. Bully is still with us, but much subdued. He knows where the door is, and that he would walk out of it without a job if he showed any signs of insubordination. What does all this mean? Does it infer that welfare work is useless? To my mind,—'No,' but it does show that one must step warily, otherwise the workers will walk all over you. We hope to install a cafeteria shortly, and this, with our rest room, will be sufficient welfare activities for us."

REDUCING BEARING FRICTION

The proper lubrication of all bearings, whether they are roll necks or engine slides, seems not to be so well understood by the average run of superintendents as might be the case, as many seem to think that all that is necessary is to supply the machine with grease or oil and let it go at that, the men accepting all wear on journals as an evil which cannot be avoided. It is true that wear on any bearing and journal cannot be prevented, but it is also true that it can be minimized to the lowest possible extent by using the right type of lubricant for differing sets of working conditions among various classes of machinery.

It has been stated that a busy blooming screw-down motor, which raises and lowers the top roll of a blooming mill, is sometimes called upon to reverse as many as 22,000 times in 24 hours. This works out at more than 15 times per minute throughout the entire period, and makes it clear that the necessity for starting and stopping very quickly is a paramount consideration in its design and operation.

Practical Ideas for Shop Executives



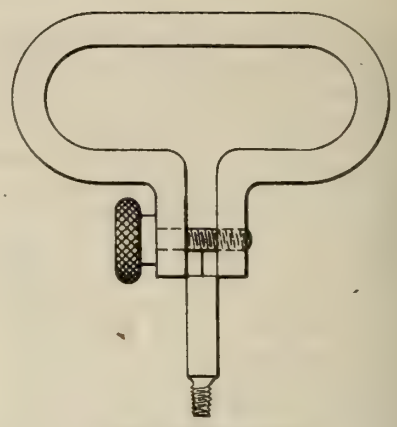
THREAD TESTING DEVICE

By Cecil H. Smith

The accompanying sketch illustrates a device constructed by the writer to facilitate the gauging of screw threads on taps and gauges. It is used in connection with precision gauging blocks.

It is much easier to detect the error in thread heads than to correct them. The object of the apparatus here shown is to enable the operator to locate the error with the least inconvenience. The device consists of a base, A, provided with a wide top surface in which is located the groove, B, along which the angle block, C, can be moved to any desired position and locked by means of the knurled D. The long dove-tailed head of this clamping bolt does not bear on the lower portion of the block, but on the beveled edges of the groove B. On the right hand end of the base is a post, E, split as shown for clamping the piece F, at the desired height. The movement of this piece is obtained by the knurled portion, G, the inner end of which is a pinion acting in a rack on the cylindrical section of piece, F. H. is the frame that carries the gauging centres I I. An ordinary electric light globe (shaded with light paper) is placed at K to direct the illumination upwards, so that it is easy for the operator to determine the error in lead.

The pieces I are ⅜in. dia., so that, when selecting blocks for testing the head, it is only necessary to select those that will give a measurement ⅜in. less than that to be tested. To gauge one and one-half inches of thread, seven threads per inch. Include 10 threads in the test which is 1.4286in. Subtracting .375in. the dimension required would be 1.0536in. After a little practice slight errors can be determined very closely.



Device to facilitate the gauging of screw threads.

TAP SAVING WRENCH

By Harry Moore

The wrench shown at Fig. 4 is advanced not so much as a time saver as a tap saver. It is intended to be used as a wrench for the smaller taps which break very easily when held in the wrench usually furnished; which may be a good wrench for the larger sizes, but which allows perhaps a little too much leverage for the smaller taps. As the squares of these taps are usually made one size regardless of the diameter of thread, very little adjustment is required in the wrench, only enough in fact to release it when the screw is loosened. As shown here a piece of ¼ rod is bent to form a handle, the two ends being brought together after slightly flattening the inside faces and cutting a shallow V. A knurled screw is used to spring the ends together sufficiently to hold the tap in place. With a holder like this the "feel" is very sensitive and the user can tell at once when the strain on the tap is becoming too dangerously near the breaking point.

A tap saving wrench.

ATTACHING PUNCHES TO HOLDERS

By F. Scriber

It frequently happens that in punch and die construction an insufficient amount of attention is given to the proper method of fastening the punches in position on the holders. They are frequently held in place by screws in such a manner that the screws will jar loose, with the result that the punches fall down and are broken, necessitating expensive repairs for which no one apparently is to blame. Another source of trouble is that the punches are put in place in such a manner that they are difficult to remove when replacement becomes necessary. The object of the accompanying illustrations is to show a few simple methods of attaching punches, and an attempt will be made to point out essential differences which make some methods more substantial than others.

Referring to Fig. 1 the view at the left shows a punch, A, which has a shoulder and a reduced shank, B; this is held in a steel plate, C, the upper end of the shank being headed over so that it is securely held in place when withdrawn through the stock which it perforates. The plate, C, is attached to the main por-

tion of the punch holder by means of screws and dowels not shown. This punch requires quite a little machine work to make and can hardly be considered as good construction as that shown to the right of Fig. 1. This punch, D, has a head, E, at its upper end, it is simply made a drive fit in the plate, F; the large head prevents it being pulled out of the plate when it is being stripped from the stock punched and its large head also provides a greater bearing surface, so that it may better withstand the end thrust of punching. Both of these examples show round punches.

In Fig. 2 are shown two examples of methods of holding rectangular shaped punches in place. At the right of this illustration the punch, A, is simply held in the holder by means of a set screw, B; it is almost impossible to keep this set screw tight enough so that the punch will not fall out by the continual jar incidental to punch press operation. This can be readily comprehended when we stop to consider that an ordinary punch press will make about sixty strokes a minute. At the left is shown a similar punch which is held in place by means of two straps, C. The punch, D, is notched at its upper sides to form a tee slot and the straps are screwed to the punch holder thus clamping the punch securely in place. At the left of Fig. 3 is shown a punch, A, dovetailed into a holder, B, a set screw, C, coming against a gib, D, securely holds this in position, and while more expensive than the last method, if well made, is very serviceable and although the screw may loosen slightly the punch will not fall down. It may work sideways if not prevented in some manner, such as for instance, by using a dowel pin of slight depth, E. At the right of Fig. 3 is shown a punch, F, which has flanges formed integral therewith; this is held in position by means of screws and dowels in the manner shown, a groove being cut in the punch holder, G, to receive the same. This is a very substantial anchorage. In Fig. 4 is shown a punch holder which contains three punches all of which are held in place by interlocking tee slots. This punch holder, A, has a groove cut in it for a depth equal to B. The centre punch C, has grooves cut in at X. The end punch, D, has flanges on it and between this punch and the centre punch is a strap, E. To the extreme left is a round punch, F, and this is contained in a carrier, G, which is flanged. A strap H, completes this arrangement together with screws and the necessary dowels (not shown). It will be noticed that in making these units interlock with each other the whole becomes held in such a manner that one punch cannot pull away without the entire arrangement loosening up.

It should hardly be necessary to mention that whenever any particular die carries an excessive repair cost through breakage, that careful attention should be given to the points brought out in the foregoing as a good deal of die trouble can be traced directly to the loosening up of the various units used in their construction. This pertains not only to the punch and holding means but also the die construction.

There are practically no metals in commercial service that cannot be successfully welded by the oxy-acetylene torch, if the proper filling metal and manipulation of rod and blowpipe are employed.

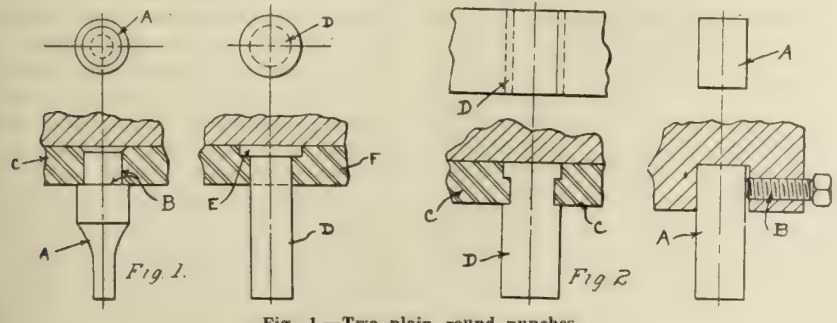


Fig. 1.—Two plain round punches.
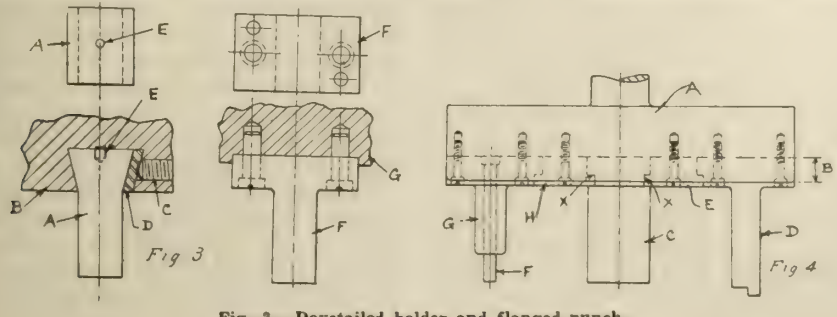
Fig. 2.—Punch held in T-slot, and plain type.



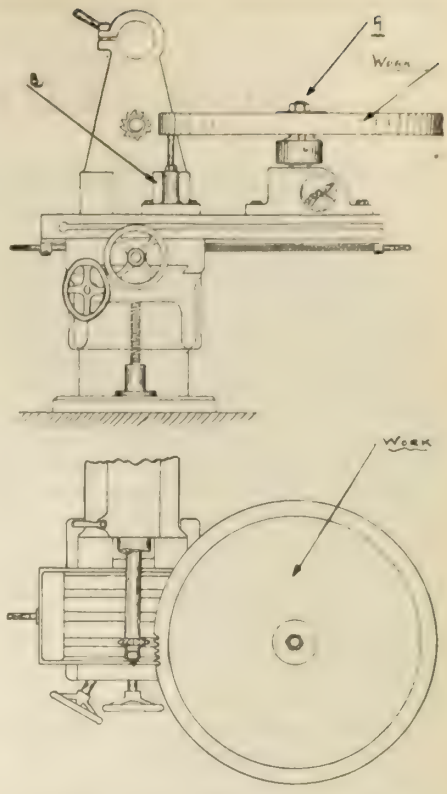


Fig. 3.—Dovetailed holder and flanged punch.
Fig. 4.—Punch holder with group of punches.

Cutting a large gear on a small miller.

CUTTING A LARGE GEAR ON A SMALL MILLER

By G. Blake

The cutting of a large spur gear does not present any difficulties if one has a machine with a wide range, but on the other hand where there are only limited facilities, the machining of large gears becomes a real problem. Our problem was to cut a spur gear, 148 teeth, 5 diametrical pitch, 30 inches diameter, 2¼ inch face. The only equipment suitable was an ordinary horizontal miller and a universal dividing head 7 inch centres. As the maximum distance from the milling machine table (when lowered to its limit) was 20 inches from top of milling table to centre of cutter arbor, to cut the gear on a mandril held between centres on the dividing head was impossible, so other means had to be adopted. The dividing head was tilted (see sketch) so that the spindle nose was vertical instead of horizontal. A stud A was made to fit the bore of the gear, having a shoulder to register the boss on and turned down on the other end to be gripped in the 3 jaw chuck on the dividing head. Next, to support the gear whilst being cut, a small jack B was used to take the downwards thrust of the cutter. The sketch shows the arm and arbor support removed so that a better view can be obtained of the method, the cutter was fed in to the required depth and then to traverse across the face of the gear, the operator raised the knee of the milling machine slowly by hand. In the manner described we solved the problem and the writer passes it on in the hope that it may help others in a similar difficulty.

New Things in Shop Equipment

GAP TURRET LATHE

A 20 in. turret lathe, the bed of which is equipped with a gap, has recently been placed on the market. The lathe has all the regular dimensions of the standard 20 in. turret lathe manufactured by the firm. The gap provides for a maximum swing over the bed of 28 ins. The length of the gap from the face of the chuck is 9-1/8 ins. The machine is regularly equipped with an air chuck, power feed for the cross travel of the cutoff rest, and power feed for the longitudinal feed of the turret. Special feeds and accessory fittings can be provided on special orders. The machine is manufactured by the Cincinnati Acme Machine Tool Co. of Cincinnati, Ohio.

OFFSET DRILLING AND MILLING ATTACHMENT

There has been recently developed and marketed, an offset drilling attachment for work where a very small clearance space is available. The tool is intended especially for drilling, milling, countersinking, and counterboring port holes and grooves in the cylinders of air-driven tools such as drills, hammers, and riveters. It is made to reach into the main bore and drill or mill the vents or ports from the inside. It may be used to drill or mill to a specified depth, to counterbore, or to mill circular, transverse, or longitudinal slots. It has, of course, other applications such as machining oil grooves, keyways or splines. Owing to the small space and comparatively long overhang with which these tools must work, practically no clearance space is allowed; and the offset or horizontal arm is as large as the bore of the air chamber and the depth of drilling or milling will permit. Both the power transmission parts and the offset arm are made of tool steel heat-treated, ground and lapped. The clearance space inside the arm is very small, so as to add to the strength of the arm. Drills, mills, and counterbores, having special shanks ground and lapped to fit the spindle in the outer end of the arm, are used. They may be easily changed and have a limited adjustment for depth to allow for grinding and setting. The attachment has a wide variety of uses and can be fitted to a large range of machines. It is manufactured by the H. G. Harris Engineering Co. of Bridgeport, Conn.

AUTOMATIC CYLINDRICAL GRINDING MACHINE

Recently there has been placed on the market an automatic cylindrical grinding machine that is intended for grinding cylindrical parts held on centres, and having diameters larger than ½ in. It is a fully automatic plain grinding machine. The principal features are the simplicity of construction and the speed of operation. It is adapted particularly to grinding shafts, bolts, valve tappets, piston pins, and similar work. The maximum length of the grind is six inches, while work up to ten inches can be held between centres. If desired it can be arranged to hold work in draw-in chucks. The machine weighs about 7,000 pounds, which fact is stated to assist materially in performing operations with smoothness and accuracy. The grinding wheel is 18 in. in dia., and can be used in faces up to six inches. Forced lubrication is furnished to all bearings. The machine is entirely self contained and power is furnished by a 15 h.p. motor through a 4-1/2 in. belt. Alternative drives of a cone pulley and countershaft, or a constant speed pulley, can be furnished. The machine controls are accessible to the operator and if necessary one operator can take care of four machines. The automatic operation enables production at high speed to be maintained. It is claimed that on piston pins 7/8 in. in diameter, and 3-1/4 in. long a production rate of five per minute can be maintained. It is further claimed that the machine requires less time to be set up for an operation than would be ordinarily required by an automatic screw machine. It is manufactured and marketed by the Warren F. Fraser Co. of Westboro, Mass.

PORTABLE MOTOR-DRIVEN GEARED-HEAD LATHE

A very novel form of engine lathe has recently been offered on the market. The novel feature consists of the fact that it is a real rugged machine, in the heavy duty class, having swings of 18-1/4 in. and 20-1/4 in., being built in two sizes. The headstock is supported by what we would describe as a cabinet leg. This leg does not touch the floor. It is supported by two truck wheels mounted on gudgeons extending from the side of the leg. Instead of a leg under the tail stock end there is a single truck wheel mounted on a swivelling device to which is attached a regular truck tongue with a tee end. In the cabinet leg under the headstock an 1,800 r.p.m. motor is located. The power is conveyed to the all geared head through the medium of a belt, fully covered by metal guards. In other general respects the lathe resembles a well built standard machine of the stationary type. The headstock provides sixteen spindle speeds in almost geometrical progression, with the use of only ten gears, all of which are heat treated. The headstock housing forms an oil-tight case for all running parts. The spindle is hardened and runs in phosphor-bronze bearings. All other shafts in the headstock run on ball bearings. The spindle nose has two diameters, one in front and one behind the threads, so as to give firm bearing surfaces to the face and chuck plates. The forward and reverse motion is obtained through friction clutches running in oil. The control handles for the reversing mechanism are located both at the apron and at the head end of the lathe, so as to be always within convenient reach. The clutches require no adjustment, and are capable of carrying a slightly heavier load than the work will require. The starting-box for the motor is mounted on top of the headstock. The lathe has a standard set of quick-change gears, locking device for tail stock spindle, and a rod and screw shift. The mounting of the motor does not increase the width of the machine, so that the machine can be moved through very narrow isles. The manufacturers are the Lehmann Machine Co. of St. Louis, Mo.

DRILL AND TAP CRIB GAUGE

Recently there has been placed on the market the "One-Glance" drill and tap crib and gauge. The device consists chiefly of a small drill crib with a drill gauge built into it. The entire crib is 41 in long by 9¾ in. wide, and contains sixty semicircular pockets 1¼ in. wide. The pockets in the lower row are 4⅛ in. long, and are intended to hold drills from Nos. 1 to 30. The upper pockets are 2-15/16 in. long and hold drills from Nos. 31 to 60. The holes for the drill gauges are located just at the ends of the pockets in hardened steel strips. These strips are inserted in the wood of the frame, in which heavy type numerals give the number of the drill required to fit each hole, as well as the drill diameter in decimals. Since the figures are ¼ in. in height, they should be readable at a distance of eight feet. The taps are placed perpendicularly in holes in the member dividing the upper and lower pockets. Holes are provided to hold three taps of each size from 14-20 to 4-36. Each set of taps is adjacent to the correct drill to use in drilling the hole for it, in order to tap a full thread. A red line extending along the board indicates the largest size of drill that could be used. It is thus possible to select a drill for either half, three-quarters, or full thread. It is unnecessary to refer to tables in order to find the necessary drill for each case, as the relation between the sizes of the drills and the taps can be observed, by noting

the relative positions of the tools in the crib. The holes for gauging the taps are drilled to the proper size, so that a larger tap than the required size cannot be placed in it, while a smaller one will fall through the board. It is thus possible for the workman to pick out the correct size of tap merely by knowing its proper position on the board. Besides serving as a container for taps and drills, the board may be used as a ready reference table of drill sizes. The board holding the pockets is carried on trunions by two posts mounted as a base, so that the whole unit is easily portable. Due to the fact that the trunions are tightly pinched in the brackets of the posts, the tray may be tilted to an angular position, and will remain so fixed. The base can be attached to the wall, so that bench and floor space can be saved. The equipment is manufactured by the Victor R. Lawson Co. of Boston, Mass.

SPEED LATHE WITH A. C. MOTOR HEAD-STOCK

There has recently been placed on the market a 12 in. swing speed lathe for bench mounting. The lathe is intended largely for wood turning in training schools and for pattern work. The manufacturers suggest that the lathe be mounted on a bench, which in reality is a chest of drawers, which extend right down to the floor, resting on legs that are only an inch or two in height. A half horsepower motor is mounted directly on the spindle of the lathe, and the motor housing is the head-stock. The 45-carbon steel spindle has a ⅝ in. hole throughout its entire length. A No. 2 Morse taper accomodates the center point. The nose of the spindle is 1⅛ in. in diameter and has V-threads, ten to the inch. On the outside end (left hand end) of the face plate a combination 8 in. pulley and face plate is mounted. This face plate can swing work larger than that which will pass over the shears. The pulley may be employed for belting the motor to auxiliary equipment. The spindle is provided with S. K.F. radial and thrust ball bearings carcied in dust-proof housings. The motor is fully enclosed. The bed is equipped with flat ways, and can be supplied in 4, 5, or 6 ft. lengths. The maximum distance between centres for the above lengths of bed are 25, 37, and 49 in. respectively. Short legs for bench use are ordinarily supplied, but long legs for supporting the lathe from the floor can be supplied. The bed is widened out under the headstock to accomodate the controller. A casting bolted to the headstock leg and to the lower part of the bed serves to fully enclose and protect the starting device. The a. c. motor is of the variable speed type. Speed changes are obtained by manipulating a handle on the front of the bed under the headstock. Four speeds are provided, name'y 575, 1,160, 1,750, and 3,450 r.p.m. The wiring between the motor and controller is fully enclosed. A tailstock, fitted with an adjustable spindle and a device for clamping it to the bed, is provided. The rest holder is clamped by means of a single handle. Each lathe is equipped with a spur and a cup centre, three T-rests, a 5½ in. faceplate, a 3 in. screw chuck, a knock-out rod for the head centre, and one right angled rest. Additional equipment may be furnished to special order. The lathe is manufactured by the J. G. Blount Co. of Everett, Mass.

SMALL ENGINE LATHES

A line of engine lathes suitable for tool rooms and automotive service stations has recently been placed on the market. There are three sizes, namely 13 in., 14 in., and 16 in. swings. The 13 in. size has semi-quick change gears, and a single back gear. It swings over the shears 13¼ in. and over the carriage 8 in. The 14 in. lathe can be equipped with single or double back gears, has quick-change gears, and swings 14¼ in. over the shears, and 10⅝ in. over the carriage. The 16 in. size has double back gears, quick-change gears, a cabinet leg under the headstock, and a swing of 16¼ in. over the shears, and 11⅜ over the carriage. A three step cone with countershaft is the regular design. Bowl headstocks are employed, and the gears are fully enclosed. The spindles are made from high carbon steel. The 14 in. lathe has a hole of 1¼ in. throughout its length. The spindle bearings are phosphor bronze. The tail stock is of the offset design to permit the compound rest to be swung around parallel to the ways. Provision for setting over the tail stock has been made so that tapers can be turned.

The quick change gears permit of cutting all standard and odd threads from 3 to 64 per inch, either right or left hand. Sliding gears are employed in the gear box. On the 13 in. semi-quick-change lathe, three changes of feed are provided by shifting a lever. Additional changes are made by means of removable change gears. A reversing lever for the feed is provided on the apron, as well as an interlocking device to prevent two feeds being engaged simultaneously. The carriage can be securely clamped to the shears for facing operations. There are both front and back gibs to the carriage. Taper gibs are used on the cross slide and the compound rest.

Standard equipment for the lathe is; —large and small faceplates, chuck plate, steady rest, follow rest, double friction countershaft, centres, wrenches, and a thread indicator. Other special attachments such as those for milling and keyway cutting, taper turning, and increasing the swing, can be furnished. The two large sizes when equipped with a 6 ft. bed can swing between centres 39 in. With a 5½ ft. bed the 13 in. lathe weighs 1,300 pounds. The 14 in. lathe with a 6 ft. bed weighs 1,700 pounds. The 16 in. lathe with an 8 ft. bed weighs 2,100 pounds. The lathes are manufactured by the Carroll and Jamieson Machine Tool Co. of Batavia, Ohio.

ALL GEARED HEAD ENGINE LATHE

A new design of electrically driven engine lathe has been placed on the market recently. Among the new features, is the one of having all the gears in the head, in mesh, constantly, the various speeds being obtained through the medium of levers on the head stock. The range of speeds consists of twelve, ranging from 9 to 350 r. p. m. The lathe is driven by a motor attached to a base-plate on the back of the single cabinet leg supporting the head stock end. This motor is belt connected to a constant speed pulley on the head stock. The drive from the pulley to the headstock is through a friction clutch.

The spindle is a heat-treated, chrome-nickel, steel, hammered, forging. The head stock is fully enclosed. The top cover of the head-stock has a removable plug which permits of ease in filling with oil, as all the gears in the headstock run in oil. A gauge glass indicates the height of the oil at all times. The lathe can be arranged to cut threads from 2 to 56. All studs in the apron have a bearing at each end, as the apron design is of the double plate type. All feeds are reversible, and the various mechanisms are so arranged that the longitudinal and cross feeds cannot be engaged while cutting threads. The head-st ck control lever is located at the right hand end of the apron, sliding on a control rod. The head-stock spindle is stopped, started, and reversed by this lever. A second lever mounted on the control rod but at the left-hand end of the apr n functions in a similar manner. The tail-stock is of the offset type, permitting the compound rest to swivel around parallel to the ways of the lathe. The tail-spindle is also made of chrome-nickel steel and is hardened and ground. A side adjustment for taper turning is provided. A constant speed motor, from three to five h. p., with a maximum speed of 1,160 r. p. m., is recommended. Some of the principal dimensions are:— actual swing over bed, 19½ in.; swing over carriage, 13¼ in.; diameter of hole in head-stock spindle 1½ in.; distance between the V's of the carriage, 14 in.; and the distance between centres on a lathe having an eight food bed is 4 ft. 2 in. The weight of the lathe with an eight foot bed is 4.75 pounds. The manufacturers are the Boye and Emmes Machine Tool Co., of Cincinnati, O.

Major Frank Williams, representing Holman Brothers' Ltd., of Camborne, Eng., has arrived in Canada and will work in co-operation with the Alfred Herbert Co. who are Holman Brothers' agents in this country. Major Williams will devote his time exclusively in developing sales on mining equipment of all kinds, such as hoisting engines, derricks, rock drills, crushers, etc.

The Noon Hour Problem

ON PAGE 29 of this issue appears an article dealing with the noon hour danger. It is a well known fact that the noon hour of practically every plant, is the period when men get together for a smoke and a chat. Almost every factory has at least one disgruntled employee and often this one man spreads discontent, and stirs up a harmonious staff into a dissatisfied crowd. Several ideas have been tried, some with great success, while other factories, using the same successful idea adopted in one plant have been bitterly disappointed when they tried to apply it to their own. It is another case of one man's meat is another man's poison.

The article appearing on page 29 is by a shop superintendent of 18 years experience, and is based on fact, not theory. For this reason, it is worthy of special consideration, and although it may not apply directly to your factory, it will at least provide food for thought.

It seems to us that any noon hour games should either be of such character that overheating would not occur or if baseball *is* played, the men should realize that it is not a championship game they are playing, but merely something to break the day's routine. The best solution is to eliminate baseball or football for even standing in the sun is exhausting in hot weather.

The value of the cafeteria is unquestioned, for if run on a no-profit basis, the workers can get pure food at low cost, this making for good health and contentment. Card games, checkers, and other games where over-exertion is not necessary, are good things to provide, but the moment that bad feelings and bitter rivalry creeps in, let it be understood that the games will be stopped if the trouble continues. It seems to us that this would have solved the difficulty mentioned in the other article.

Good music is very desirable, and several have found that this helps to solve the noon hour problem. Some use gramaphones, while others again gather an orchestra together from the staff, allowing them a reasonable time off for practice. Concerts are held at noon, and we have visited several of these entertainments and enjoyed them thoroughly.

Comfortable rest rooms are also very desirable, but one point the superintendent seems to have overlooked in his article is the value of good books. Note that we say good books, not the usual trash. Not that they should be all business books, but when fiction is included, be sure of the author. Several firms have now installed libraries, and while skeptical at first, as to whether their employees would read such high class literature or not, they have, without exception, been agreeably surprised. The only reason the workers did not read such books before, was their inablity to afford them. Good books soothe the mind, make for contentment, and stir up the seeds of ambition. The noon hour problem is nearer solution to-day than it ever was, but the secret does not lie out on the athletic field, but in the comforts of an easy chair, good music, and a good book.

Eliminate the Danger

STORING and handling oils is a dangerous task, and should be treated as such. Instead, we find many plants content to stick their room off in some dark corner, trusting to luck that nothing will happen. Constant handling without disaster is pointed to by some as ample proof that oils are not dangerous, but the folly of this belief is shown clearly in the article appearing on another page of this issue.

It tells of a case where gasoline fumes were carried outside to a lighted lamp 30 ft. away from the building, taking fire and flashing back, the result being, the structure was entirely consumed. In spite of this fact, we find many concerns, with their entire capital invested in a business, giving little thought to their oil room, which perhaps is their greatest danger point.

Luckily, all plants are not alike, for we viewed a splendid installation recently, where oils and paints were stored in an excellent fireproof manner. Even where used in another form, an arrangement was provided whereby, should the material catch fire, it would be extinguished within two minutes. Should the extinguisher fail to function, they had still another safety device, which would automatically let the unignited liquid run outdoors. This firm realized the danger, and knew that once they let a fire get beyond their control, their complete factory would be doomed. It pays to play safe when handling oils, and if you have not yet provided for proper storage, there is still time, but there won't be—after the fire.

* * * *

Link Up Your Efforts

WHILE passing through an Ontario manufacturing plant recently, we were much impressed with the care taken to check up parts going through the factory. The inspection system was simple, but thorough, and the method of watching costs, arranging for jigs and fixtures, etc., had been well thought out. The manager of this plant knew exactly the cost of his product, what it took to sell the goods, and knew even to a fraction of a cent, the profit made. He had eliminated guess work, with the result that while several plants in his locality were operating on part time, his factory was employing a full staff and running right up to record business.

In these days of keen competition the importance of keeping close tab on costs is further emphasized, and if a plant manager hopes for success he must stop groping around in the dark. After a cost system has been installed and is working smoothly, use it to discover if operation costs as shown on cards can be reduced. Make a point to have the plant superintendent constantly on the lookout for better manufacturing methods. In the plant we first referred to the superintendent is a live wire, eager to discover new methods, and in several cases, without purchasing any additional equipment, he has reduced the operation cost as much as one fourth of the original figure. This means a considerable saving, but he accomplished the result through constant study of the task on hand. Link up the efforts of the factory and office, show the superintendent where you believe the operating costs are too high, and in many cases even this hint alone will bring forth surprising results.

Improved Buying Develops in Many Lines

Increased Sales of Pig Iron and Steel Commodities—Small Supplies Moving Freely—Strike Not Yet Seriously Affecting Production of Steel—Prices Likely to Advance

CUSTOMERS SHOWING INCREASED INTEREST

WHILE nothing of outstanding importance has developed in Canadian markets, there is a hopeful note sounding in many lines of industry. The strength that was reported in the iron and steel section last week continues to retain the interest of dealers, and this also is true in other branches of metal working activities. The advance in bars recently recorded in the States has not yet been felt on the local market, as dealers here follow the lead of the Canadian mills, and so far, these have not advanced quotations no commercial products. With U. S. mill prices higher, the difference in exchange works to the advantage of Canadian dealers and the ultimate price to consumers here remains virtually the same.

No change is noted in the general condition of the non-ferrous metal situation, but the undertone is improved as a result of the better inquiry of the past week. There is a feeling that consumers are showing a little anxiety regarding the future and may desire to protect themselves against a possible advance caused by curtailed output.

Pig iron is the one local commodity that has been directly influenced by existing conditions. Canadian producers report a heavy demand for pig and believe it is caused by the fear that the next few months may result in the closing of some of the smelters owing to the shortage of coke.

The movement of machine tools remains at a low level, dealers stating that an occasional sale is made, but that little big business is in prospect. The encouraging factor in this line is in small supplies and reports indicate that the volume of sales are not only held, but in many instances gradual improvement is shown.

In old materials the market continues unchanged, with prices firm and demand light. Dealers are encouraged, however, by the better movement in commercial materials and feel that this will eventually influence the buying of scrap.

The coal strike is the main influencing factor in respect to developing conditions in the steel and metal industries, and while no serious effect is yet noted, the passage of time and gradual depletion of raw material supplies, may create a condition that will require some able handling to prevent a tie-up throughout the entire country.

Dealers and merchants in this district are encouraged by the better volume of business that is in sight for the near future.

Toronto

April 26

EVERY indication points to a steady improvement in all lines of industry. While much of this results from seasonal demand there exists a belief in many minds that the better business is of a permanent character and that the summer will continue to show the gradual return to a more normal condition in all branches of trade. With few exceptions the reports are of an encouraging nature.

Iron and Steel.—The improved demand that was reported last week in iron and steel markets continues to feature the situation this week. Consumers are buying more freely, and while many are doubtless protecting their stocks against the possibilities of the future, the fact is impressed on many dealers that a steady increase is taking place on the present actual consumption of iron and steel commodities. Sales show that the demand does not come from any particular industry, but the range is wide and distribution of such a character as to indicate slow but gradual improvement in almost every trade. Construction material is moving freely and likewise the gauge sizes of sheets and plates.

While no pronounced anxiety is shown in local circles regarding the coal strike in the States, there is considerable interest manifest in the possible duration of the strike. The stocks on hand, together with present production, is sufficient to take care of all requirements for a couple of months, although some manufacturers are taking steps to regulate the consumption of available coal supplies. Should no settlement appear possible at the end of a couple of months, the situation will take a more serious turn and the restriction of production of basic metals will effect the manufacture of semi-finished and finished lines, and this will doubtless be reflected in higher quotations in all lines of iron and steel products.

Local prices on iron and steel are still firmly held, and advances in the States have not been reflected here, as Canadian dealers continue to quote the normal price of $2.75 on bars, stating that they take their cue from the mills here and so far no advance has been made. Imported product, however, would likely carry the advance, but as one dealer remarked: "The difference in the exchange almost makes up for the American advance, so that the situation, as yet, is not materially changed." The basic prices are unchanged as follows:

Iron bars	2 75
Steel bars	2 75
Reinforcing bars	2 75
Steel hoops	3 75
Tire steel	3 00
Spring steel	6 00
Band steel, No. 10 gauge and 3-16 in. base	3 25
Small shapes	3 00

Pig Iron.—A steady increase in demand has been experienced by pig iron producers in Canada since the first of the month, and it is stated by dealers that this is largely due to the fear on the part of users that the market will be dominated by the coal strike and that production will be curtailed beyond the normal requirements of present consumption, a condition that would naturally result in sharp advance in prices.

Non-ferrous Metals.—Little change is reported in this market, although inquiry has been better during the week. Dealers are interested in coal strike developments, as the metal situation will be indirectly effected by a restricted supply of coal and other raw materials. Local prices are firm and unchanged as follows:

Lake Copper	17 00
Electric Copper	17 00
Castings, copper	16 50
Tin	34 00
Spelter	7 25
Lead	6 75
Antimony	00 8
Aluminum	26 00

Scrap Metals.—The old material situation remains the same with light movements of supply. There is a slightly better undertone, which may be developing in sympathy with the iron and steel activity but the actual sales of scrap are on a par with previous weeks. "Slight fluctuations in price take place from time to time," remarked one dealer, "but this cannot be taken as a normal condition, as it is more the result of a specific trade than market trend." Following are present nominal quotations:

Copper, light per 100 lbs.	8 00
Copper, crucible	10 50
Copper, heavy	10 50
Copper wire	10 50
No. 1 composition	8 50
New brass cuttings	6 00
Red brass turnings	6 00
Yellow brass turnings	4 75
Light brass	3 50
Medium brass	4 50
Scrap zinc	3 25
Heavy lead	4 00
Tea lead	3 00
Aluminum	10 00
Boiler plate, per gross ton	9 00
Heavy melting steel	10 00
Axles (wrought iron)	16 00
Rails (scrap)	10 00
Malleable	11 00
No. 1 machine cast iron	16 00
Pipe, wrought	6 00
Car wheel	16 00
Steel axes	15 00
Mach. shop turnings	6 00
Stove plate	14 00
Cast boring	5 00

Machine Tools and Supplies.—Nothing of special character has developed in machine tool circles. Sales of heavy tools are light, but well distributed, and nothing big seems to be in prospect. One dealer stated that he had several good things on the way but that the prospect-

ive purchasers are holding off until the last moment, and that this seemed to be the prevailing attitude of all users, just buying when they are forced to. The movement of smll tools, and supplies, on the other hand, is showing a steady increase and few dealers are complaining of the volume of business in these lines. One dealer stated that sales have steadily increased since the first of the year.

Oils and Greases.—A steady business is reported in oils and compounds and prices are firm and unchanged as follows:

OILS AND COMPOUNDS

Castor oil, per lb.	34½
Royalite, per gal., bulk	21
Palacine	24
Machine oil, per gal.	33 00
Black oil, per gal.	17 50
Cylinder oil, Capital	61 50
Petroleum fuel oil bbls., net	9 90
Pure turp., single bbls. gal.	1 35
Linseed oil, raw, single bbls.	1 00

Montreal

April 26.

NO DECIDED change can be reported in the general trade conditions for the past week. In many lines there have been slight or even fair improvements, but on the whole the situation can best be summed up in the statement that, locally, business has only done a little better than hold its own. The marked improvement in the steel business in the United States has not been reflected in Canada to any great extent. The mills here are only producing on a small percentage basis, and are prosecuting a very vigorous sales campaign. Prices on most steel and iron products are at a very low level. This factor, coupled with the fact that the volume of business is small, makes it difficult for producers to show any profit at all. Many deals show dead losses. For this reason manufacturing costs have been receiving very close scrutiny and a large number of economies have been effected. These economies will enable the mills to turn out material at very reasonable figures when increased demand appears. Building operations are being pushed to a marked extent all over Montreal Island. The demand for all kinds of building material is exceptionally good, although somewhat below that of the high mark set during the past few years. Some new developments are expected in pig iron, but trading locally has been very light. Very little change is noted in the machine and wood working tool field. The non-ferrous metal market is very quiet locally.

Iron and Steel.—It is expected that the steel situation in the next few weeks or months, will be directly influenced by the developments in the coal strike. For some time past the local mills, dealers, and jobbers, have predicted an upward revision in prices. Up to date no actual advance has been announced, although there is definite stiffening in quotations. Local business has been fair. The jobbers and mills have a fairly good supply, when the light demand is considered, and all orders have been promptly filled. If the demand increases, through conditions arising out of the coal strike, there is no doubt but that quotations will be materially increased. It is extremely difficult to forecast the future even a few days ahead. The reported improvement in the U.S. steel industry has not yet influenced local markets.

Structural steel is still moving at a fairly satisfactory rate. Merchant bars are a little more active than they have been, but the demand is still rather light. It is confidently expected by representatives of the two mills that roll rails that orders will be forthcoming at an early date. For some time past these orders have been expected, and although up to the present such have not come through, it is only reasonable to assume that the placing of this business is not far distant. Plates are quiet. Sheets are in better demand. The orders booked in the last few weeks for both black and galvanized sheets are very satisfactory, when all things are considered. English galvanized sheets are stiffer but as they can now be imported directly by water, a saving in freight can be effected which will tend to offset the advance. Other lines are moving fairly well. There are no changes in the local quotations which are as follows:

Iron bars	2 75
Steel bars	2 75
Reinforcing bars	2 75
Steel hoops	3 75
Tire steel	3 00
Spring steel	6 00
Band steel, No. 10 gauge and 3-16 in. base	3 25
Small shapes	3 00

Pig Iron.—During the week pig iron has been advanced two dollars a ton. No. 1 iron is now quoted locally at $31.80 per ton. Heavy bookings have been reported here, and one producer states that sales of considerable volume have been placed in the United States. It is also claimed on good authority that there will be a further price advance in the course of a week or ten days. The bookings of some of the American furnaces are greater than has been expected and deliveries are being given at future dates. The coal strike has accelerated the situation, but it has not been entirely unexpected.

Machine Tools and Shop Supplies.—Iron working tools are in small demand at present and there is no change in the situation. Wood working tools are in better demand but even in this department business is spotty. Supplies are still moving nicely. It is hoped that the April turnover will be in excess of March and there is every reason to expect this. Jobbing and contract shops are showing a desire to come into the market a little more freely, but the increase in business is not great as yet.

Non-Ferrous Metals.—Markets in the United States and Great Britain are somewhat more active than they are locally. Quotations are somewhat stiffer in these quarters and in sympathy local figures are up. There is no increase in the local demand, but at the same time the small amount of business moving is not diminishing. The local quotations are as follows:

Lake Copper	16 75
Electric Copper	16 50
Castings, Copper	16 25
Tin	35 00
Lead	6 75
Spelter	7 25
Antimony	6
Aluminum	23 50

Scrap Metals—There has been a somewhat better demand for scrap metals locally and in a few instances quotations have been increased. The real source of this improvement originates in the States, where demand has developed to a marked degree. Locally the demand has increased, as many of the smaller shops are enjoying a better business. In fact, the last two weeks have been more encouraging to dealers than any time for several months. Local quotations are as follows:

Copper, light per 100 lbs.	8 00
Copper, crucible	10 50
Copper, heavy	10 50
Copper wire	10 50
No. 1 composition	8 50
New brass cuttings	6 00
Red brass turnings	6 00
Yellow brass turnings	4 75
Light brass	3 50
Medium brass	4 50
Scrap zinc	3 25
Heavy lead	4 00
Tea lead	3 00
Aluminum	10 00
Boiler plate, per gross ton	7 00
Heavy melting steel	9 00
Axles (wrought iron)	17 00
Rails (scrap)	10 00
Malleable	10 00
No. 1 machine cast iron	18 00
Pipe, wrought	7 00
Car wheel	18 00
Steel axes	16 00
Mach. shop turnings	4 00
Stove plate	16 00
Cast boring	3 00

Pittsburg

April 26.

IN THE past few days production of coke in the Connellsville and Lower Connellsville region has been approximately stationary, at about one-third the rate in March. There have been a few fresh strikes, at individual works, while on the other hand some men have returned to work and the working forces are better aligned for production. The shipments of coal out of the region are reduced more than the production of coke in the region. The regular union strike, in the Pittsburgh and other union

districts, proceeds without incident and no developments in it are to be expected in the near future. The union strike was expected to last anywhere from two to six months. The non-union strikes, which are important only in Western Pennsylvania and West Virginia, are expected to begin waning about May 1. These non-union workers are not accustomed to striking, while with the union coal miners striking is quite a habit, as there has been a "suspension" almost every time the biennial scale has come up in the past quarter century. Since the war there have been two off-date strikes, a big one late in 1919 and a group of little ones in the late summer of 1920. The probability is the non-union strikes will be over before the regular union strike comes to a head. The United Mine Workers cannot pay strike benefits to its own men, not to speak of the non-union men it has induced to strike.

On the whole, the effect upon pig iron and steel production of the Connellsville region strikes has been less than might have been expected. Quite a number of blast furnaces, particularly in the merchant group, are banked, and a few steel works have been closed, but production has increased in districts that draw their fuel from elsewhere. For instance, the Illinois Steel Co. is operating at 83 per cent, while the steel industry as a whole is running at something like 70 per cent., or at a rate in steel ingot production of between 36,000,000 and 38,000,000 tons a year. The rate was about 35,000,000 tons at the end of March and 30,000,000 tons at the end of February. Thus steel production as a whole has not decreased since the general coal strike started April 1, but it has not increased as it was increasing during the first three months of the year, the rate in December having been under 20,000,000 tons a year in ingots.

As a matter of bare fact there is little doubt that the coal strike has been a blessing in disguise for the steel market. There would have been trouble if buying and production had kept on increasing at the phenomenal rate of the first three months of the year, for no one can possibly imagine that consumption of steel has been increasing at any such rate. After a drastic liquidation in stocks of steel in 1921 the country was stocking up, partly in anticipation of the coal strike and partly in anticipation of better business. Now the coal strike is retarding further increases in production while it is stiffening steel prices, some of which, particularly prices for bars, shapes and plates, had gotten altogether too low, far below the cost of production.

Steel Prices.—Bars, shapes and plates are now very firm at 1.50c, which has been the ordinary market quotation for nearly a month, but has hitherto been subject to more or less shading in the case of particularly desirable orders. Some mills have largely withdrawn from the market by setting their prices at 1.60c or 1.65c, but obtain some prompt business, in small lots, at these figures. Independent wire mills continue to hold nails at $2.50, while the Steel Corporation remains a seller at the old price of $2.40. Hoops and bands are up $2 a ton to 2.00c, the price established just previously by the hot rolled strip mills. There are some purchases of small lots of sheets at the prices as recently advanced, $3 a ton to 2.40c. for blue annealed, 3.15c for black, 4.15c for galvanized and 4.50c for galvanized sheets, but the amount of selling and contracting done before the advance now seems larger than was at first estimated. This develops from the fact that some sheet mills, that use purchased sheet bars instead of making their steel themselves, have been in the market to buy sheet bars, not having embraced fully their opportunity in March to buy sheet bars at the then market of $29, against their sales of sheets at the old prices. Apparently they thought they could advance the sheet market without the steel mills advancing sheet bars in turn. The lowest quotation on sheet bars is $33 as on account of the coal strike the steel mills are disposed to save their steel making capacity for their own finished products.

Further stiffening in the steel market, quite likely with some definite price advances, is in prospect, due both to the coal strike directly and to the general change in sentiment whereby there is a sellers' market in steel instead of a buyers' market. Taking steel products as a whole, purchases made in the first three months of the year are going to prove distinctly profitable.

The strength of the steel situation at the moment, and for the nearby future, is well recognized although the more conservative observers have strong doubts as to its permanence. In many quarters one hears the opinion expressed that the movement has come about six months too soon and that, but for the possible saving influence of the coal strike, it was almost certain to have an inglorious ending this summer.

Pig Iron Much Higher.—In view of the merchant blast furnaces that pig iron has been selling at far below the cost of production, it is entirely natural that the great majority of the furnaces in this general territory should have withdrawn from the market when coke supplies were so greatly reduced by the Connellsville region strikes. It is difficult to find sellers at all, and an actual market cannot be quoted. What is definitely found is that one cannot buy basic pig iron at less than $22, valley, though it is not certain one can buy at that price. The pressure is to buy basic iron, but foundry and Bessemer certainly would not be sold at less than basic, hence the market can be quoted as being not under $22, valley, for Bessemer, basic or foundry, against prices of $19.50 for Bessemer, $18 for basic and $19 for foundry before this coke development began. When a full supply of coke becomes available again, as it may possibly in as little time as three or four weeks, the furnaces will undoubtedly endeavor to hold pig iron prices where they stand at the time, and those prices may, and probably will be, higher than the $22 figure just mentioned.

Coke, on the other hand, is hardly likely to be established at a much higher level than obtained in the first three months of the year. Just now no regular market on coke is quotable, because there is so little to be had. In furnace coke there are a few carloads offered here and there, not enough to run one blast furnace, and so the furnaces do not bid for it, their idea of price being $3.50 in view of the low prices at which they owe pig iron to customers. In foundry coke a little demand has developed, though the great majority of foundries stocked up freely in anticipation of trouble, at $4.25 to $4.75, the market ruling in March. A few carloads in the past week have brought about $6.25.

THE BASIC INDUSTRIES

There is now substantial evidence that the basic industries are, in the United States, on the up-grade. The United States Steel Corporation is now operating at 60 per cent. of normal capacity, which is about twice what it was last year. Agencies in Canada representing American steel producers report a satisfactory increase in the volume of orders. In Nova Scotia, orders from abroad for iron ore brighten a prospect that is otherwise dull. The labor disputes prevent the resumption of coal mining on a large scale. It cannot be said that Canadian steel fabricating plants have a cheerful outlook just at present; but the tide is on the turn, and when the banks feel at liberty to release funds, there will be enough business in construction work and in providing equipment to make our steel men smile once more.

NEW STEEL DEVELOPED

As the result of research work carried out by H. H. Ashdown and others at their Openshaw works at Manchester, Armstrong, Whitworth & Co. have produced a steel known as Vibrac. What is claimed for the new steel is that in addition to responding satisfactorily to even higher mechanical requirements, particularly in respect to elastic limit, than those obtained from nickel-chrome steels, it may, subject to any normal treatment, after tempering, be either furnace cooled or cooled in air, thus cutting out risks of distortion, and yet will give higher impact values than nickel-chrome steel treated under the most favorable conditions.

The composition of a welding rod should be of such a nature that during the welding the metal is not so liquid as to run easily over the unfused metal, covering up impoperly fused and oxidized surfaces.

News From the Industrial Field

The **Fulmanite of Mercury** plant at Prescott started operations Monday.

J. Arena, of Smiths Falls, is preparing to build a business block to replace the one destroyed by fire last fall.

Archibald & Holmes, 709 Yonge Street Toronto, has been awarded general contract for erection of the addition to the Conservatory of Music, approximate cost being $50,000.

James Hird, formerly in charge of the Cost Department at W. H. Banfield & Sons, is now associated with the Commercial Fixture Co., Toronto, manufacturers of electric fixtures.

J. Johnstone, architect of Vancouver, B. C., has been instructed to draw plans for the preparation of the addition to the Telephone Exchange, the cost of which will run about $40,000.

Goldstein Manufacturing Co., Toronto, are now located in their new building on Beverley Street. They will specialize in the manufacture of copper and brass tubing, likewise seamless rods.

The steamer St. Lawrence recently purchased by Canadian interests will be in commission again this season among the Thousand Islands. She is now being remodelled in drydock at Kingston.

An entirely new installation of heating and ventilation for the Myrtle Street public school of St. Thomas, Ont., has been recommended by Donald Stewart, consulting engineer, of Windsor and Hamilton.

Announcement is made of the incorporation of Water Products Ltd., with a capitalization of $500,000. They will manufacture machines for making oxygen and hydrogen by the electrolytic decomposition of water.

The Robertson Construction Co. of Niagara Falls, Ont, has secured the contract for the erection of a new sub-station for the Hydro Electric Division at Niagara Falls. The cost of the structure will be about $67,200.

The Steel Trough and Machine Co. Tweed, Ont,. have opened an office in Montreal to take care of their Quebec business, under the management of R. L. Welsh. Their Montreal office will be Room 216, St. Nicholas Building.

Robt. Gardner & Sons of Montreal, are manufacturing the machinery and equipment that will be installed in the biscuit factory for David & Frere at Maisonneuve, Que. The contract price of machinery will be about $50,000.

Drummond, McCall Co., 28 Victoria Square, Montreal, will erect a warehouse on Wellington Street. The contract for the wrecking of the old building has been let to the Hochelaga Demolishing and Cartage Co., Montreal.

The Ottawa Auxiliary Bible Society has purchased a site for the erection of a permanent home and the financial campaign to raise $10,000, which is a condition of two anonymous donors of $5,000 each, is already in full swing.

Negotiations are now in progress for the erection of a large addition to the Misericordia Hospital, Edmonton and it is expected work will be started early this summer. The proposed extension will be north of the present structure and the estimated cost will be approximately $250,000.

The Canada Iron Foundries of Montreal, have obtained a contract for 10,000 feet of class "C" six inch cast iron pipe at $68.00 per ton for the city council of Edmonton. The council has also awarded contract for lead pipe at $10.50 per 100 pounds, to the Metals Limited of Edmonton. These figures are f.o.b. Edmonton.

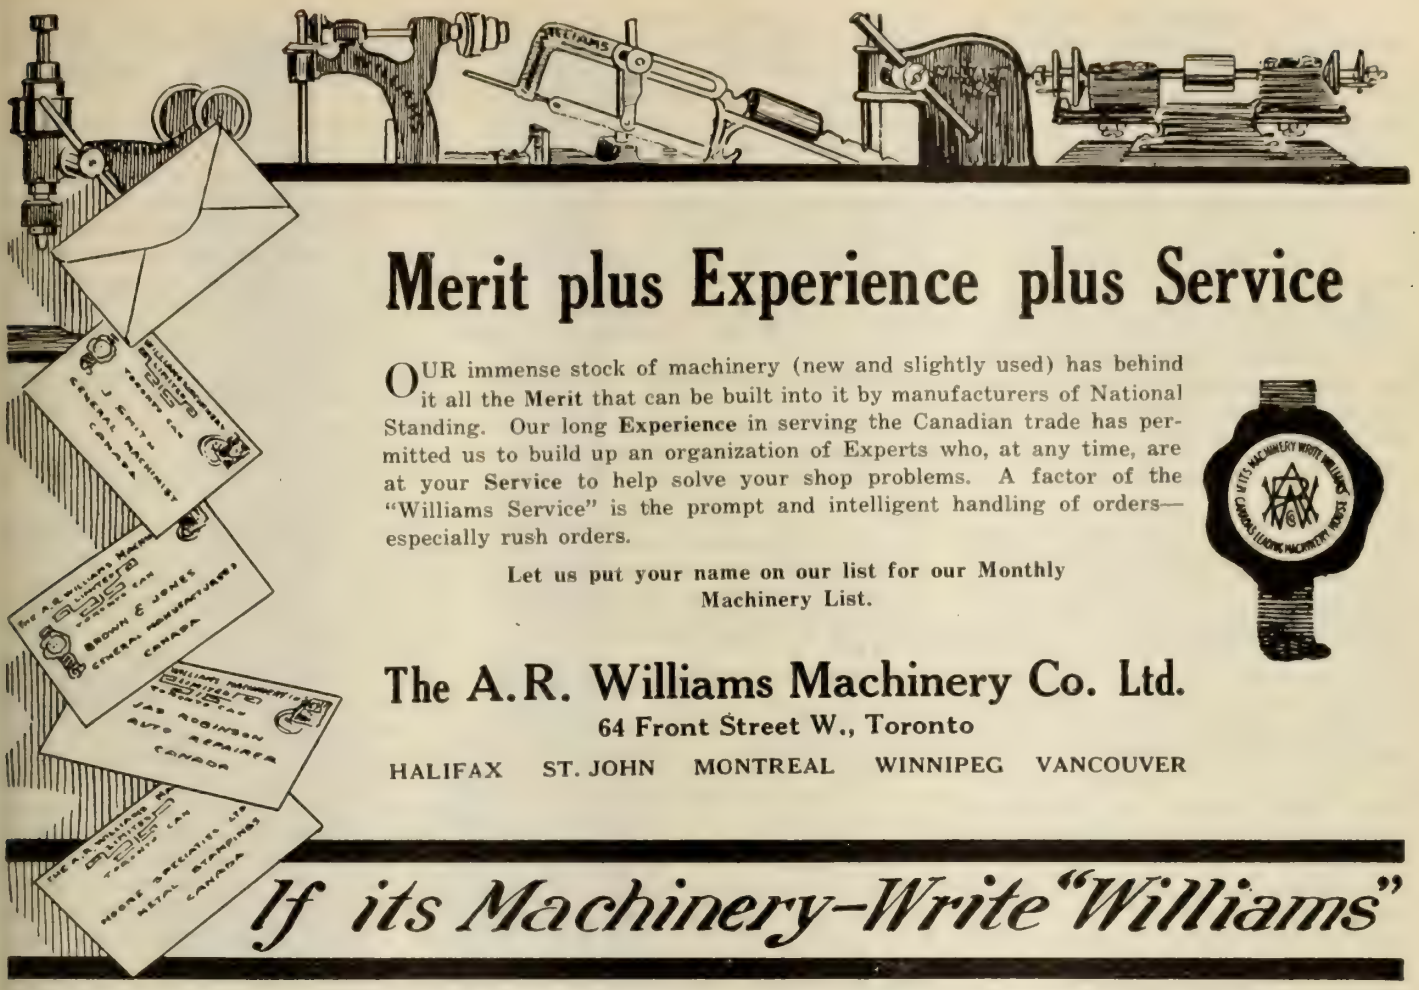
Tenders for the masonry, brick and carpentry work on the new civic hospital will be received May 4. The trustees will then call for tenders for heating, plumbing and ventilation of the main building and possibly also for the power house and building for female help, leaving only the nurses' home, plans for which are well under way,

At a recent meeting of the Non Ferrous Metals Division, Waste Trade Dealers' Association of America, Edmond L. Frankel, general manager of Frankel Brothers, Toronto, was elected president for the forthcoming year. Mr. Frankel is to be congratulated on being elected to such an honourable position.

The Provincial Government of Alberta have passed estimates recently which include $2,000,000 for extension to the Provincial Government Telephone system. A new normal school and technical institute receives $562,000. Construction and improvement to railway lines in the province controlled and endorsed by the Alberta Government will receive $3,218,000.

The Dominion Wheel and Foundries Co., 131 Eastern Avenue, Toronto, report that they sold more car wheels during the first three months of the present year than during the entire year of 1921. They also delivered some fairly large castings from their jobbing department, so that on the whole they have no complaints to make regarding business and prospects for this year.

With the amicable settlement of the dispute between the members of Local 71, Plumbers' and Steamfitters' Union and the Master Plumbers' Association, there would appear to be no possibility of any trouble on May 1 in the building trades. The painters and plasterers do not expect any, the Laborers' Union has accepted the award of the conciliation board of 45 cents an hour, and the electricians expect to sign a new agreement within a few days.



The general contract for the construction of the collegiate institute and technical school of Guelph, Ont., has been awarded to the Yates Construction Co. of Hamilton. The contract price, namely $252,500, is to include all work with the exception of plumbing, heating and ventilation. The contracts for the last three mentioned has been awarded to W. C. Edge and Co., of Ottawa, at a cost of practically $54,000. The building will be of reinforced concrete.

The Hydro-Electric Power Commission of Ontario has decided to start work on the construction of a new line on the St. Lawrence between Morrisburg and Brockville, to provide for the increased load created by the establishment here of the Eugene Phillips Electrical Works. Work will be carried on from both ends of the thirty mile stretch of line and all the insulators and cross arms will be changed, owing to the increased voltage from 25,000 to 44,000.

Reports from Saskatoon, Sask., announce the following contracts closed for construction work. A new chemistry building at the University of Saskatchewan will be commenced shortly, the estimated cost to be about $440,000. Bennett and White of Calgary are the general contractors. Green and Lister of Winnipeg have received the contract for plumbing and heating. Wathton Electric Company of Saskatoon have obtained the contract for the electrical work.

The following construction work has been added to the industrial activities for Hamilton for the present year. W. H. Cooper has received a contract for the construction of a Masonic Temple. The estimated cost for this building will be $300,000. Three additional sections will be built to the grandstand in Scott Park. The contract has been awarded to the Hamilton Bridge Works Co. the estimated cost to be $16,500. An addition, costing about $150,000, will be added to the "Towers," the former residence of George E. Tuckett, which sometime ago was acquired by the Ancient and Accepted Scottish Right.

Once again the ice-breaker "J. D. Hazen" has changed hands and is now back to its original owners, the Dominion Government. The recent purchase

Merit plus Experience plus Service

OUR immense stock of machinery (new and slightly used) has behind it all the **Merit** that can be built into it by manufacturers of National Standing. Our long **Experience** in serving the Canadian trade has permitted us to build up an organization of Experts who, at any time, are at your **Service** to help solve your shop problems. A factor of the "Williams Service" is the prompt and intelligent handling of orders—especially rush orders.

Let us put your name on our list for our Monthly Machinery List.

The A.R. Williams Machinery Co. Ltd.

64 Front Street W., Toronto

HALIFAX ST. JOHN MONTREAL WINNIPEG VANCOUVER

If its Machinery—Write "Williams"

was negotiated by Assistant Deputy Minister of Marine, Mr. Hawkin, who is now in France. The figure mentioned is $400,000. It will be remembered that sometime early this spring the Canadian Government was negotiating with the Canadian Vickers of Montreal for the construction of a new icebreaker at a cost of $1,500,000. However, these plans were abandoned with the result that the previous icebreaker constructed by the Canadian Vickers Company some years ago will soon be back on Canadian waters.

Building operations for the coming season in Montreal include the following: Rebuilding of the Church of the Sacred Heart, which was destroyed by fire recently, will be started shortly. Anglin-Norcross Limited have received contract for the construction of a large medical building on the south-west corner of Guy and Sherbrooke Streets. The building will be ten storey high. A new public school at an estimated cost of $350,000 will be constructed by the Protestant Board of School Commissioners in Notre Dame de Grace. Kenneth C. Rae is the architect. The Catholic School Commission of Montreal has acquired a site for the erection of a large residence and school, estimated cost of both being about $200,000.

At a recent meeting of the representatives of the machinery manufacturers of Toronto held at Exhibition offices at Canadian National Exhibition at Toronto, George E. Irving was in the chair and the meeting discussed plans for a new Machinery Hall. The proposed sight is at the east end of the grounds facing the new road that is contemplated by the Harbour Commissioner. Prospects are that the building will have a frontage of 450 feet and will contain approximately 125,000 square feet of floor space. The building will be constructed on unit system, the first unit to contain approximately 80,000 square feet of floor space. It is stated that 25 per cent. of this space has already been subscribed for. The estimated cost of the building is $300.000.

High water in the Ottawa river, during the past week played havoc with local lumbering industries. It is known that 60,000 logs owned by John R. Booth, Ltd., and other local lumbering industries broke loose from their berth. The sorting gap and booms of the Shepard and Morse Lumber Co. were swept away. It is estimated that some 300,000 logs just west of the dam held back the flood waters from the Chaudiere Falls, water lots, and power driven machinery of various Chaudiere companies. The J. R. Booth and E. B. Eddy industries carried on with great difficulty and in both plants the pulp mills were only working part time owing to the high water having submerged the water wheels. The stock of sulphur in the E. B. Eddy sulphite mills has been considerably damaged.

Time and again the Campbell power plant, owned and operated by J. M. Campbell, president of the Kingston Navigation Co., has come to the aid of the city when the Hydro failed and this was again the case recently when the severe electric storm late one morning damaged the Hydro lines west of Belleville and cut off Kingston's supply. The Campbell power from Kingston Mills was switched on and carried the load very successfully. But for this very valuable source of supply, the city of Kingston would have been "stalled" on many occasions.

A committee appointed by the Sydney Mines Town Council to look into and report on the matter of changing and improving the water service system of the town has recommended that the ratepayers be asked to authorize the borrowing of $100,000 or whatever sum they deem necessary for the purpose. The report was approved except that the amount was named at $200,000, and a ratepayers' meeting will be called for the purpose.

The town of Bridgewater, N. S., is taking separate tenders for erection of a fire hall and for the plumbing and heating for same, tenders to be in by May 8th.

A petition for the winding up of the Acadia Shipping Co. is to be presented in the Supreme Court and the hearing is to be on April 25. The petitioner is E. K Spinney Ltd., a body corporate, of Yarmouth.

The Dartmouth, N. S., water committee will purchase an air compressor and gasoline engine, 5 tons of half inch lead pipe, body gate valves, and cast iron pipe, the possible requirement of which will be thirty-five tons.

It has been announced at Queen's University, Kingston, that the authorities there intend to go ahead with the erection of the new library building this summer. At the present time the plans are being prepared and the work on the foundation will be pushed along as quickly as possible. The building will be of stone and will mean a great deal of work for stone-cutters and masons. It is fully expected that it will give a long term of work to many men. The new edifice is to be erected on the corner of Union Street and University Avenue, north of Ontario Hall and adjoining Gordon Hall.

The Grand Trunk shops at Point St. Charles will close down on Friday, April 21 until May 1. Notices to this effect were posted in the shop last week and it is stated that the action has been taken largely because of slackness in traffic, resultant on the coal strike in the United States. At the offices of the vice-president it was stated, that up to the time of the coal strike, business had been steadily improving, and that it had been hoped that the Saturday off would soon become a thing of the past in the Point St. Charles shop. The continuance of the coal strike, however, is making a difference in traffic which renders retrenchment necessary until conditions improve.

Prof. L. A. Zufelt, superintendent of the Kingston Dairy School, received the proposed plans for the new dairy school building here, to replace that destroyed by fire a short time ago. The architect employed by the Ontario Government has submitted a couple of sets of plans to the superintendent. Prof. Zufelt knows exactly what is required and he and the architect have been conferring together. It is expected that work on the new building will commence in the near future, so as to have the school ready for the opening of the fall course, near the first of September. The building will be fireproof and the steam plant to furnish the power separate from the main school.

As a result of recent investigations in Japan respecting the possibilities of that country obtaining Canadian manufactured goods, a very promising field has been opened up in the matter of exporting grinding wheels to Japan. Tentative inquiries made on all sides on this subject have elicited great interest and several important firms in Japan have expressed their desire to be put in touch with a Canadian manufacturer of grinding wheels, in a position to export same, with a view to acquiring the sole agency for such. While it is impossible to state now just what actual business would be forthcoming as a result of correspondence interchanged between the Canadian manufacturer and the Japanese importer of grinding wheels, still there is a demand, and directly trade conditions brighten it is safe to say that this demand will increase more and more.

Among the interesting articles which will appear in forthcoming issues are the following:—Automatic Work Produced at High Speed, May 4; Storing Small Tools Increases Their Life, May 11; Proper Piling of Goods Reduces Costs, May 18; Saving Money By Means of the Turret Lathe, May 25.

A correspondent in Belgium in response to a recent enquiry as to the possibilities for Canadian machine tools in that country says: "I see no reason why specially efficient Canadian machine tools of a lighter type should not find a market here when exchange improves, say by even a few francs on the dollar." He refers to the fact that Canadian saws, forks, rakes, hoes, valves and much Canadian agricultural machinery are already on sale in Belgium.

The contract for the construction of the new chemistry building at the University of Saskatchewan has been allotted to Messrs. Bennett & White of Calgary, Alberta, whose tender of $400,000.00 was the lowest of the eight received. David R. Brown, Esq., of Montreal, is the architect to the University. The contract for plumbing, heating and ventilating has been awarded to Messrs. Green & Litster of Winnipeg, at $115,000.00, and the Wheaton Electrical Co., of Saskatoon, were the successful tenderers for the electrical work at $20,000.00. The work will commence on this building during the next two weeks.

The Williams Tool Corporation have built at their Brantford plant a 20 inch pipe threading machine—the largest of its kind on record—for delivery to the International Petroleum Co. in Peru, South America. This machine weighs 11 ton, the head alone having a weight of 3,000 pounds. Just recently the machine was put through some severe tests in the presence of E. C. Kitchen, Toronto, representing International Petroleum Co., representative of the Canadian Fairbanks Morse Co., through whom this business was placed, and members of the engineering and sales staff of the Williams Tool Corporation. In their oil well operations the International Petroleum Co. use miles of casing pipes, lengths of which are joined together by means of a twelve inch coupling. A thread of about six inches is therefore required on each end of the pipe—and using a thirteen inch pipe as a test the machine made a satisfactory performance, producing a clean cut job on a six inch casing thread. The strain on a thread and coupling when a casing is being pulled after boring operations, is sometimes more than 200 tons. Delivery of the machine will be made about the 1st May.

CANADIANS SHOULD SUPPLY SAMPLES OF GOODS

One of the features of export business which Canadian manufacturers have not thoroughly grasped is the need of supplying samples in making a bid for trade. One Canadian firm, states A. B. Muddiman, Acting Canadian Trade Commissioner in Bristol, Engand, failed to secure orders through this cause, taking no less than twelve months before they supplied samples to the British buyer, who in consequence lost all interest in the placing of the order. Once specifications and designs have been submitted, the Canadian manufacturer should make speed with the samples in order that the English commission house may push sales. The Germans are well aware that the secret of success in marketing woodenware is to have their samples speedily on view.

FIFTY DOLLAR TAX ON TRAVELLERS

The following letter, which has been received at this office from H. M., Senior Trade Commissioner in Montreal, depicts the attitude assumed by city officials in the capital of Newfoundland.

Dear Sir:

I have to-day received notification from the Deputy Minister of Customs in Newfoundland, to the effect that the Municipal Corporation of St John's has recently passed an act imposing a tax of fifty dollars ($50), on all commercial travellers entering the city. This tax is not payable outside the city limits.

Yours faithfully,
H. M. Senior Trade Commissioner,
in Canada and Newfoundland.

OBITUARY

John E. Davey

John E. Davey, manager of the Manitoba Steel Foundries, died recently at his home in Selkirk, Man. The late Mr. Davey was born at Whitby, Ont., and for a number of years was associated with the Canadian Brake Shoe Co. at Sherbrooke, Que. He moved west six years ago, and for the past four years has been with the Steel Foundry Co, holding the position of manager for the last three years.

It Was Just A Matter of Grinding

The same set of Thread Chasers cut these two threads.

Observe what a clean cut the Chasers gave on this open hearth stock after they had been correctly ground. Note how neatly the Chasers curled out the chip. Before given the right form of grind, the Chasers simply pushed out the stock.

How To Grind Thread Chasers

Instructions for the Care of Thread Chasers are very completely given in a 27-page booklet published by us.

The Book Is Free

To those having the care of Thread Chasers. It is printed and distributed with the hope that the rules given will be followed, and if they are, it will be the means of an inestimable saving of time, money and trouble.

If you have anything to do with the care of Thread Chasers, ask us for the book. Although there is no charge for the book, it is full of value. It will cost you the price of a postage stamp only, and will save you trouble, increase your value to your employer and save a lot of money that is needlessly wasted in time and scrapped work.

St. John, N.B. Vancouver, B.C.

GENERAL ELECTRIC TO BUILD VACUUM TUBES

The Canadian General Electric has undertaken the construction of vacuum tubes for use in wireless instruments. The supply has been limited in view of the immense demand for this very necessary part of radio equipment and a heavy investment has been made for the manufacture of these tubes. At the present time the output is approximately 200-300 per week, but with the installation of more equipment this output will be brought up to 200 per day. The bulbs or tubes so far produced have been what are known as the U. V. 200 and the U. V. 201, the former tube for the detection of wireless signals and the latter for detection amplification.

Considerable damage was caused by the bursting of a large generator at the power house of the Ontario Power Company last week. No definite reason is given for the cause of the accident but it is possible that racing of the rotor was responsible, the excessive centrifugal force resulting in dislocating some portion of the heavy mass. It is likely that some time will elapse before repairs are completed.

In last week's issue Brown and Sharpe Co. was credited with supplying the data and cuts for the article on page 24. This should have read the Pratt and Whitney Co.

F. C. Wilson of the firm of Williams and Wilson, Ltd. of Montreal, sails on April 29th on the new White Star steamer Regina after spending the winter in Europe.

W. H. Winterrowd, chief mechanical engineer of the Canadian Pacific Railway, gave a paper before the weekly meeting of the Engineering Institute of Canada on Thursday, April 20, treating on the modern refrigerator car. Mr. Winterrowd stated that in the United States and Canada there were 153,000 of these cars, and that they carried practically all the perishable food that fed the two nations. It was pointed out that the Canadian Pacific had spent a great deal of money in trying to apply mechanical refrigeration to this type of car. The experiments were successful from an engineering point of view, but were not economically commercially. Owing to widespread points of origination it was best to have cars complete in themselves. The problem of insulation was the great study at present, and second only to insulation was efficient air circulation. The upkeep of these cars was a difficult proposition as the wear and tear of traffic quickly broke down the insulation.

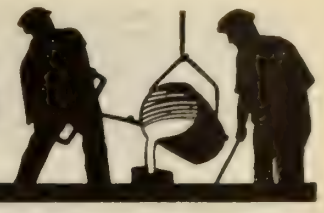
P. S. Howes of the Hall Engineering Co. of Montreal, in a recent interview stated that the contract and repair business, which was very dull with his firm toward the latter part of the year, commenced to improve about the middle of January, and this improvement has continued right up to the present time. For some time past the shop has been employing a night shift in order to get out the work. No particular line of work appears to be in evidence, but the present state of affairs is accounted for by the fact that the firm has sought business very aggressively and no job was too small to accept. Mr. Howes states that many invoices for less than one dollar are mailed out of the office. With the opening of navigation, ship repairs will provide for the company a great deal of new business that was not available during the winter months. In order to prepare for the additional volume, changes in the interior arrangement of the Jurors Street shop are being made.

Oil Tempered Steel Springs

for every purpose and the best for each use.

Special styles of all kinds to order.

THE CLEVELAND WIRE SPRING COMPANY
Cleveland, Ohio U.S.A.



WEAR IN BEARINGS

Viewed under a powerful microscope, the most highly polished pieces of metal resemble a nutmeg grater; there are many pin points sticking up, with all pores in metal, tool marks and other irregularities that, taken all together, help to produce friction. When the oil on a bearing squeezes out, these irregularities and pin points interlock, with pin points breaking off; this is termed wear. Tiny particles of metal are then carried by the oil into the bearing parts, thus acting as an abrasive. The use of graphite grease containing a large percentage of graphite entirely overcomes this state of affairs.

In order to obtain a high grade weld by the oxy-acetylene process it is necessary to fuse the edges of the base metal and the welding rod at the same time, and to obtain an intermingling of both metals.

Where To Buy Your CASTINGS

WANTED

CASH REGISTER WANTED—SINGLE DRAWer. Receipt printer. Must be in excellent condition. Box No. 807L Canadian Machinery.

"It Pays to Advertise"

"One of the most persistent advertisers in the history of success was Robinson Crusoe. He knew what he wanted—a ship—and he put up an ad for one. He flung a shirt on a pole, at the top of his island; that, in the language of the sea, was plain to every sea-faring man.

"The circulation was small—there was no other medium—but Crusoe kept at it, despite the fact that he got no inquiries for a long time. He changed his copy—as one garment after another was frayed out—and in the end got what he wanted.

"Suppose Crusoe had taken down that signal after a time and declared 'Advertising doesn't pay,'—where would he and his story be now?

"Put up your signal and keep it there. Crusoe advertised under very discouraging circumstances. You've got a sure thing—it is only necessary to have the patience, persistence, and pluck of Robinson Crusoe—and the good ship 'Better Business' will tie up 'longside your pier."

List of Directory of Dealers will be found above Advertising Index

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

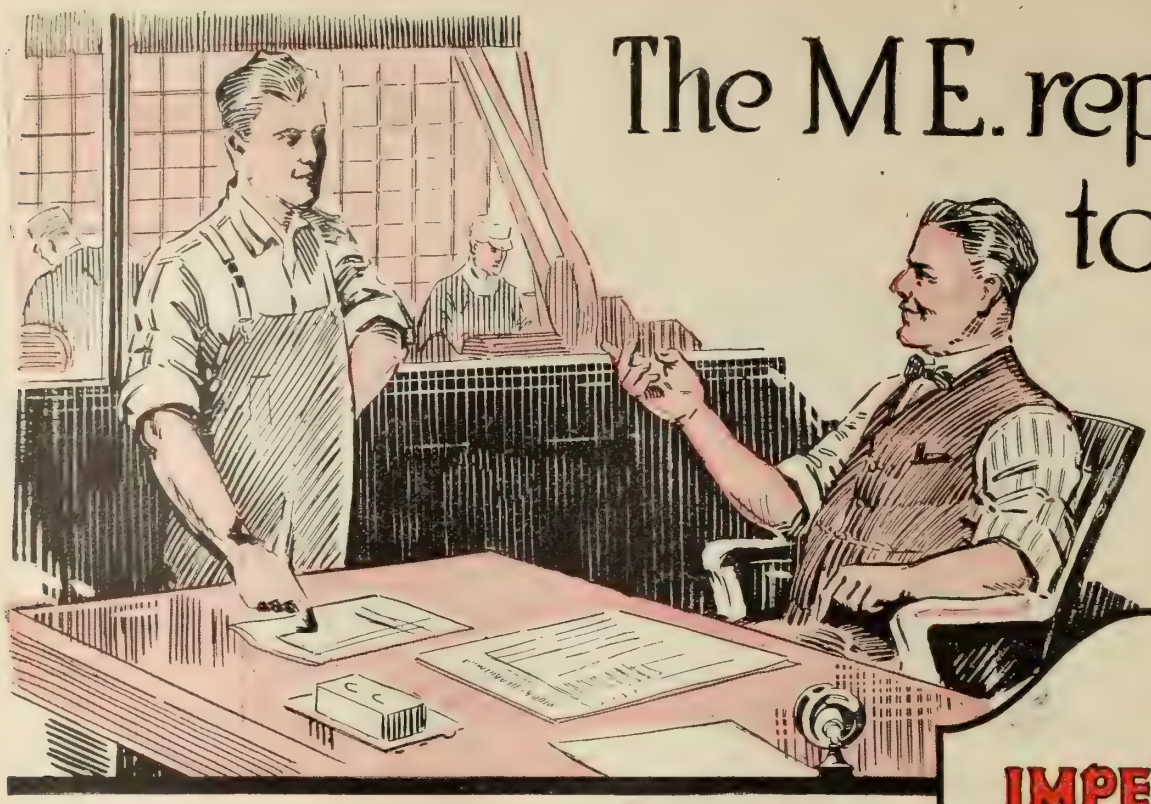
SKF

Wherever Misalignment is a Factor

THE operation of your machine will not be successful unless its bearings function in complete harmony with other parts. Deflections in the shaft, weaving in the frame and other causes may create severe stresses in all parts of the bearing, unless the latter has some inherent means to compensate for this misalignment.



The SKF marked self-aligning bearing operates on the same principle as the ball and socket joint and is therefore capable of taking care of the severest misalignment. Moreover the aligning action is positive, immediate and automatic.

The self-aligning bearing is a product of the Canadian SKF Co., Limited and is sponsored by the SKF Industries. Its manufacture embodies all the minute care, precision and quality for which the mark SKF stands. The world-wide experience of this organization is put at your disposal, free of any obligation on your part.

Canadian SKF Company, Limited

TORONTO - - - MONTREAL

The M.E. reports to the W.M.

It's a real pleasure for the Mechanical Engineer to go over his report with the Works Manager when everything is running like clock-work, due to Imperial Lubrication.

Out-put shows a good increase. Operating costs are lower than ever before. Repair expense and depreciation percentages have fallen off. And most surprising of all is the fact that lubrication costs have actually been reduced

Hundreds of plants, using Imperial Lubricants exclusively, testify to savings up to 35%. It will pay you to call in an Imperial Engineer to prescribe for your plant. Write to 56 Church St., Toronto.

Make Your Decision Now to Be in

ROCHESTER

JUNE 5th

to June 9th

Every Canadian Foundryman Should be sure to be There

ARE you interested in keeping your foundry practice right up to the minute? Are you interested in placing your methods on bigger, better, more profitable foundation? Then be sure to be at the next Annual Convention of the American Foundrymen's Association at Rochester. There will be lectures, discussions and exhibits—and an entertainment program that will surpass the best of past.

You are expected to be present and freely partake of all the good things this great occasion makes available.

You are urged to participate fully in the technical sessions and all other convention activities.

The scope of the American Foundrymen's Association embraces the foundrymen of Canada on the same basis as those of the United States. Be assured that a most cordial invitation is extended to one and all to be present at Rochester and enjoy the greatest convention and exhibit yet held by the foundrymen of North America.

American Foundrymen's Association

140 S. Dearborn Street, Chicago, Illinois

LONGEST SERVICE

We make these three right.

1. Exacting analysis of the physical and chemical properties of our steel insures a uniform product.
2. Intelligent workmanship constantly striving to produce the better tool yields the Pratt & Whitney quality.
3. Rigid inspection of the work in process and of the finished product guarantees tools for longest service.

The finished product must be right

Enlarged photo of "Acorn" Die and Holder. Note the compactness of the whole. Conical cap gives concentric adjustment—extremely accurate.

This is only one of many GTD tools designed to increase production and reduce cost.

Study the Evidence in Favor of the "Acorn" Die

Four well-known concerns which regularly use GTD "Acorn" Dies furnished the data from which the above chart was compiled—among them the Singer Manufacturing Company, the Wheeler-Schebler Carbureter Company and the Century Electric Company. Through the courtesy and co-operation of these people we were able to formulate an exact comparison between the performances of "Acorn" and other dies, under typical but totally different working conditions, in diverse fields.

The result speaks for itself: shows plainly that the remarkable productivity of the "Acorn" Die offsets by 433% its higher initial cost; shows also—what is of prime interest to die users—*the comparative cost per thread.*

We base our claims for GTD small Tools on their performances; and our engineers are ready to co-operate in effecting a typi- GTD reduction in cost. Write today.

Buy Your Belting

Like You Buy Tires

—BY MILEAGE!

If a tire purchaser ever forgot to buy mileage but bought instead on a low price basis he would find himself the loser by several thousand miles of service — altogether out of proportion to the price difference saved.

The same thing happens when you forget to buy belt mileage.

Buy a cheap, poor quality belt and the moment you put it on a pulley it commences to flap, stretch and waste power. It soon cracks, splits and goes to pieces. It demands constant attention and is a source of continual expense. Its cost per mile is high! On the other hand note the economy that comes from buying mileage in

GENUINE OAK

D·K·McLAREN

Genuine British Oak Tanned

LEATHER BELTING

Made from the best leathers obtainable; tanned by the British Oak Tanning process — the most approved method known to man —every D. K. McLaren Belt has the toughness, pliability and freedom from stretch that makes for long, power-saving service.

Only the back portions of the choicest hides are used in making D. K. McLaren's Belting. Oak Tanning increases strength and long-wearing qualities. As a result the cost per mile is low!
Let us quote on suitable belting equipment.

—and when the cutter was taken from the furnace he found—

That its cutting edges were hard and clean—no scale—and did not require to be ground. It meant much to have their edges clean and true to shape.

That's the kind of results you can get with Hoskins Electric Furnaces. The heat is clean and the temperature control is right under your thumb. The man who does the heat treating does not have to fuss around trying to get the right temperature—he takes care of the **tools,** and **not** the **furnace.** He gets greater production and better tools.

Hoskins Electric Furnace will save you money. Not just for tool rooms are they an economy but wherever metal is heat-treated.

Tell us the work you want done and ask for catalogue No. 122.

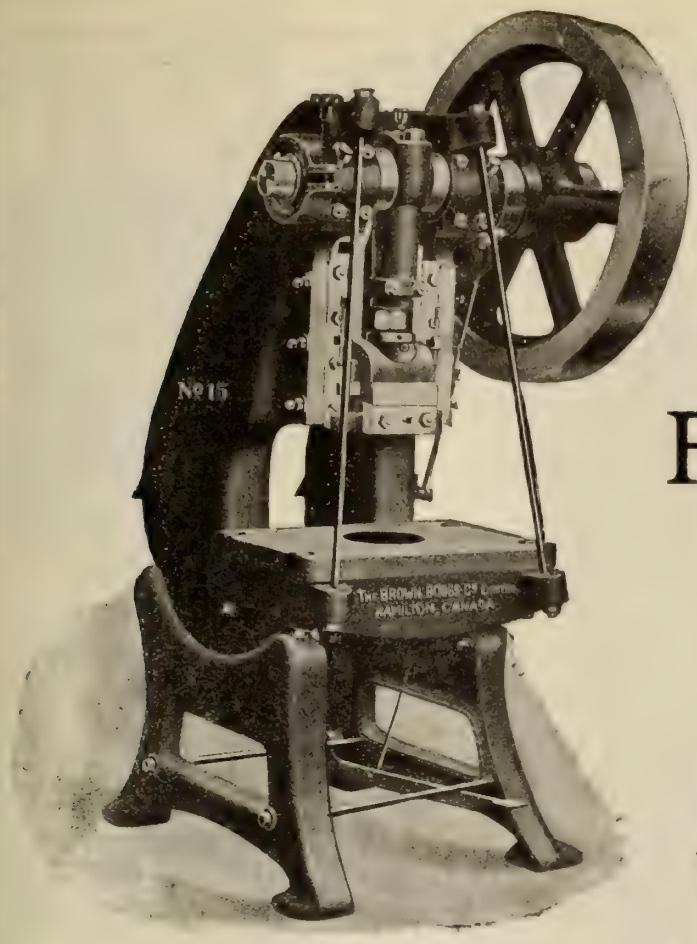
MADE IN CANADA

Hiram Walker & Sons Metal Products
LIMITED
Walkerville, Ont.

It is just as unreasonable to attempt a filing job with a file that has begun to get dull as it would be to run a machine without oil.

Full service from a file is possible only when the teeth cut keenly.

Discard a file as soon as it ceases to do this, and buy a new one.



To get long-lasting efficiency, specify one of these brands:

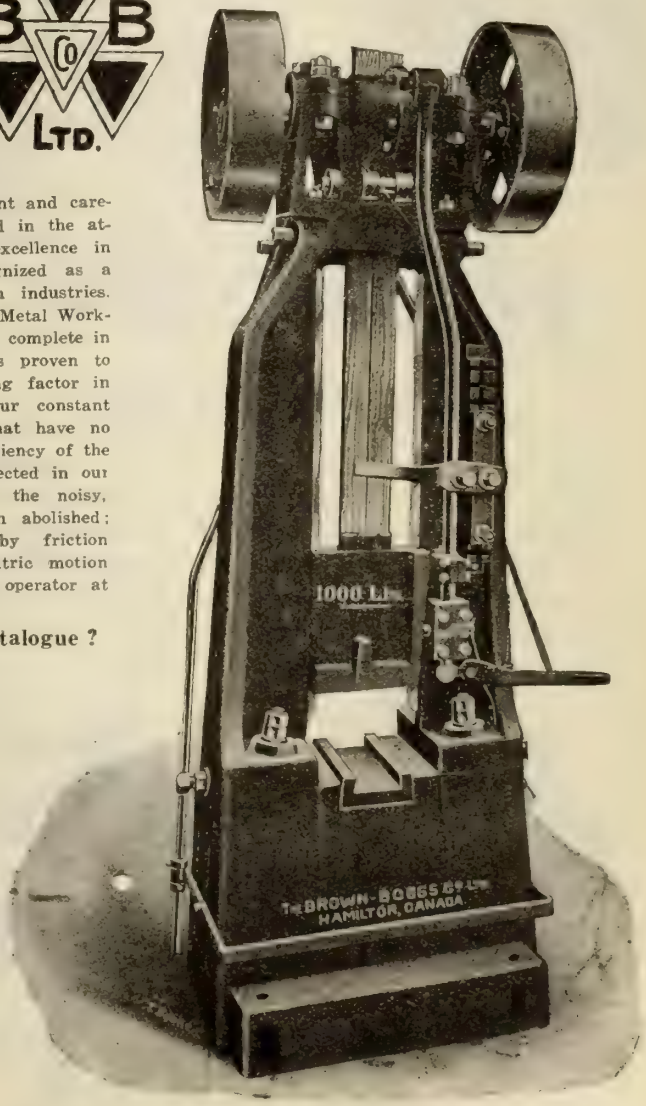
EFFICIENCY SIMPLICITY RELIABILITY

Machine efficiency is based not so much upon productivity during short periods as upon steady consistent output month after month. This is especially true where the commodity must be produced to meet a competitive market.



B B Co Ltd.

No. 140—Double Crank Trimming Press.

Years of exhaustive experiment and careful manufacture have resulted in the attainment of a mechanical excellence in B-B products that is recognized as a standard by nationally-known industries. Our line of Presses and Sheet Metal Working Tools is most modern and complete in every detail. Experience has proven to us that simplicity is a strong factor in ensuring reliability, hence our constant aim to eliminate features that have no direct relationship to the efficiency of the machine. This policy is reflected in our latest B.B. Hammers where the noisy, old-fashioned gears have been abolished; the hammer being lifted by friction exerted by a powerful eccentric motion under perfect control of the operator at all times.

May we send you a Catalogue ?

KEMPSMITH

No. 2 UNIVERSAL

Thirty-two years ago the Kempsmith Company began its career in a small one-storey frame building. To-day there are four main buildings, aggregating 106,000 square feet of floor area, besides various storage sheds, etc. Every building of the plant is a model of its kind.

It has always been, and will continue to be, the purpose of the Kempsmith Company to produce machines of the highest quality only, suited to the most advanced practice.

Every machine, whatever size or type, is put to test under cuts and conditions purposely more severe than it will encounter in even the most progressive shops, and when it leaves our factory it has our positive and definite guarantee back of it.

Literature will be gladly sent upon request.

Effective Cooperation

THE three newspapers you see illustrated here belong to the MacLean Technical Group.

If you are a manufacturer of equipment that can be used in machine shops, metalworking plants, power plants, or foundries, one or all of these papers can give you effective cooperation in increasing sales.

Tell the consumer about your products in the columns of these publications. The men who buy industrial equipment read them. Your products may have advantages over other products of their kind.

Tell the consumer what they are. Create a desire in his mind to buy your lines when ordering from the dealer.

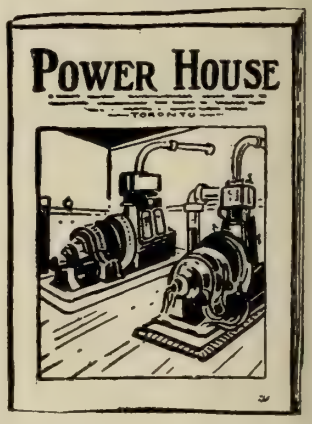
An effective message in MacLean Technical Newspapers will prove effective cooperation for the promotion of sales, and the group you can use to greatest advantage includes:

CANADIAN MACHINERY
AND MANUFACTURING NEWS

POWER HOUSE

CANADIAN FOUNDRYMAN
AND METAL INDUSTRY NEWS

Canadian Machinery serves the iron and steel and general metal working industries.



Power House serves steam, electrical, water and gas power plants.

Canadian Foundryman serves the grey iron, steel and non-ferrous foundries.

Each of these papers covers their respective fields almost exclusively. They are "Canadian National" in scope and are read by the men you are anxious to reach—proprietors, managers, superintendents, purchasing agents and foremen. Attract the attention of these men with a strong appeal in their favorite technical newspaper—the MacLean service staff will assist you.

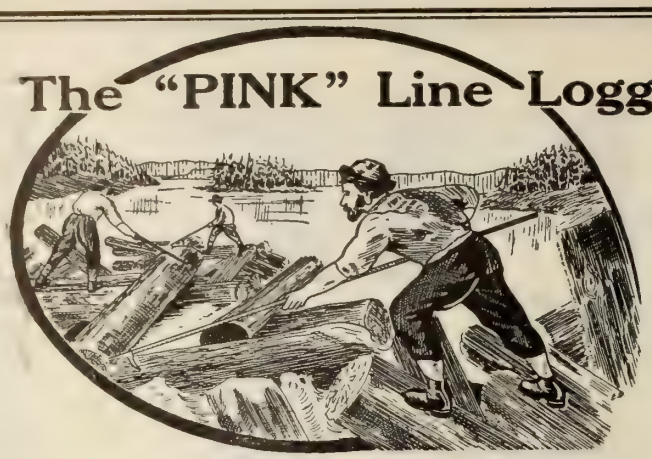
ACME

Heading and Forging Machines

Unequalled Production!

There are many instances on record where Acme Forging Machines are increasing production to an almost incredible volume. In one shop 2,500 Socket Wrenches are being produced in each 9-hour shift. Still this is not exceptional for Acme Forging Machines. Acme machines are today not only producing forgings of all kinds in greater quantities but are producing forgings impossible on any other machines.

Send for catalog describing the ability, power, simplicity and productivity of these finely built tools—do it to-day.



The Acme Machinery Company

4530 St. Clair Avenue, Cleveland, Ohio.

Silent Pinions

Use Only High Grade Material

Gear Data for Your Note Book

Cut This Out,—More Coming Later

FROM HAMILTON GEAR AND MACHINE CO., TORONTO.

The best rawhide, such as we stock, comes from the Dutch East Indies. It is much superior to the American cowhide, but any rawhide is subject to injury from excessive moisture, oil or heat.

For such severe conditions use "Celeron," a manufactured composition of bakelite and cotton. Rawhide or Celeron pinions are stronger than cast iron and, because the material is elastic and resilient, it absorbs the dynamic energy of the shocks and vibration. This absorption is the secret of their silence, and of their strength at high speeds. They can be run as high as 2,800 feet per minute pitch line speed, though 2,000 feet per minute is the recommended limit. Do not overload non-metallic pinions. Consult us on special drives.

CUT GEAR COSTS
WITH THE
New Production Gear Shaper

The new production Gear Shaper, illustrated, has been designed to cut gear costs. It incorporates every feature necessary in a gear cutting machine to obtain this result, and still one of the outstanding features of the Gear Shaper principle—accuracy—has been maintained.
It is designed to cut one gear at a time and at a speed which eclipses all other methods.
All operating levers are at the front of the machine, permitting a number to be bolted together and operated as a unit, one 6 H.P. motor furnishing ample power for **10 machines.**
It incorporates to the fullest extent the three principal requirements of production—high speed, accuracy and simplicity of operation.
See illustrated article in all technical **magazines.**
Send for our booklet, "A New Development in Gear Cutting," which has been prepared for the benefit of Engineers and Production Managers interested in the best gear cutting equipment available.

Cleco Pressure-Seated Air Valves

Bowes Air Hose Couplings—Cleco Never Slip Hose Clamps — Cleco Grooved Hose Nipples and Hose Clamp Tool

STYLE O.F. is an Outside Thread Female Pipe End. Made in sizes ⅜-inch to 1½-inch.

STYLE I.F. is an Inside Thread Female Pipe End. Made in sizes ¼-inch to 1½-inch.

STYLE H.F. is a Female Hose End with spiral shank to insert into the hose and has groove for the Never Slip Hose Clamp. Made in sizes ¼-inch to 1½-inch.

STYLE H.M. is a Male Hose End with spiral shank to insert into the hose and has groove for the Never Slip Hose Clamp. Made in sizes ¼ inch to 1½-inch.

STYLE O.M. is an Inside Thread Male Pipe End. Made in sizes ⅜-inch to 1½-inch.

STYLE I.M. is an Inside Thread Male Pipe End. Made in sizes ¼-inch to 1½-inch.

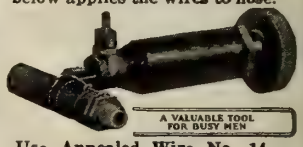
The Male and Female Ends of Bowes Couplings interchange in sizes ¼-inch to ¾-inch. Sizes 1-inch and 1¼-inch interchange. The 1½-inch ends interchange only with themselves.

BOWES COUPLINGS

Are instantly connected or disconnected.
They are absolutely air-tight under all pressures.
They quickly pay for themselves by stopping costly leaks.
They interchange in sizes most commonly used.
They have no loose parts to be mislaid or lost.
They are made of brass and will not rust.
The U-shaped Gasket interchanges in couplings ¼-inch to ¾-inch.

CLECO AIR VALVES.

Style R.A. **Style P.O.** **Style A.**



Style P.O.—Made in sizes ¼ in., ⅜ in., ½ in., ¾ in., 1 in., 1¼ in., 1½ in., 1¾ in., and 2 in. Pipe Outlets. Inlets are one pipe size larger.
Style A—30° Angle Valves, are made in sizes ½ in., and ¾ in.
Style R.A.—Right Angle Valve, made in sizes ¼ in., ⅜ in., ½ in., and ¾ in.

CLECO GROOVED HOSE NIPPLES

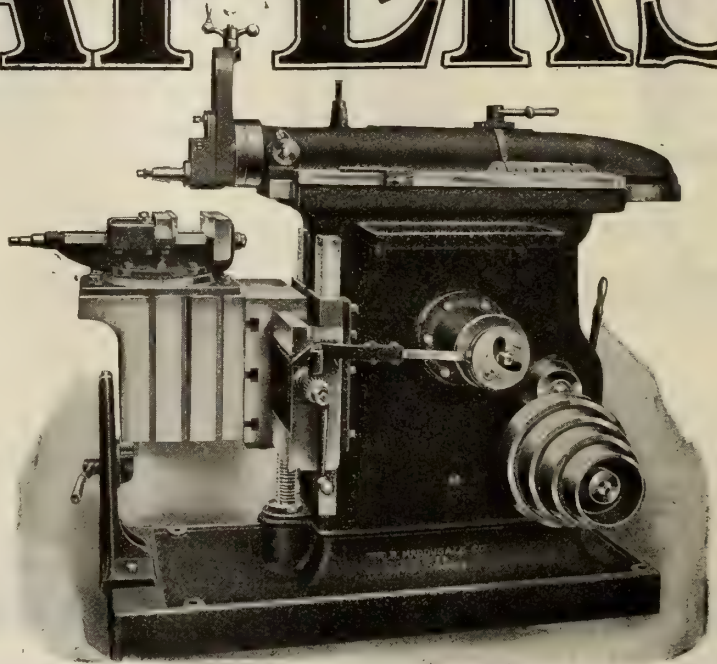
Grooved Nipples when attached to the Hose with Wire Clamps as illustrated cannot "blow out." Wire clamp tool shown below applies the wires to hose.

The Lighting Hose Clamp Tool illustrated applies wire clamps at a cost of 1½ cents each.

In stock: Riveting and Chipping Hammers, Air Drills, Emery Grinders, Sand Rammers, etc.

Use Annealed Wire No. 14

IMPORTANT:—The Small Leaks in your "AIR LINE" mean serious loss in DOLLARS. Have you any idea of the amount of "Air" wasted in small leaks at your connections? Air Leakage through 1-16 in. opening equals 5.32 cu. ft. per minute at 80 lbs. It will pay you to install Bowes Couplings and Cleco Valves, which will stop costly leaks.



Bulletin No. 50, mailed on request.

THE MODEL HOSE LINE illustrated shows correct styles of couplings and valve to use and proper way to attach the Cleco Never Slip Hose Clamps to Bowes Couplings. No "blow-offs" can occur when "Cleco" Clamps are used.

YOUR CHAIN OF CONFIDENCE—AND

BROWN & SHARPE

MACHINISTS' TOOLS

The manufacturer in equipping his plant with Brown & Sharpe Machinists' Tools links together an unbreakable chain of confidence —a chain that starts with his receiving clerks, and never ends.

FIRST LINK

Brown & Sharpe Machinists' Tools accurately test the size of incoming material to see that it meets specifications. The first link in the chain of confidence is established—your certainty that your stock is of specified sizes.

SECOND LINK

Brown & Sharpe tools and gauges check up the accuracy of your machine production. The faith of your operators in these fine tools helps them to work with sureness and speed. Another link is joined to the chain—your confidence in the quality of your production.

THIRD LINK

At the final inspection, Brown & Sharpe Tools place the seal of your approval on your products. If your products conform to the tests of these fine measuring instruments—your products must be right.

You are willing now to let the customer be the judge. Here is the third link in the chain—your confidence in the accuracy of your products.

ADDED LINKS

Tell your customers that your factory is equipped with Brown & Sharpe Tools. Then every new customer adds a link to an unending chain of good will and confidence in you and your products.

People have faith in the dependability and quality of products made with the help of Brown & Sharpe Machinists' Tools.

It rests with you to determine how long and how strong your chain of confidence will be.

Send for Catalog No. 28
which describes 2,000 tools.

TRUE BEARING SURFACES GROUND WITH NORTON ALUNDUM GRINDING WHEELS

Tedious, slow and costly "scraping" has been successfully replaced by a grinding fixture and a Norton Alundum grinding wheel.

To insure the necessary accuracy, the grinding wheel must be of an abrasive, grain, and grade to "cut true" without loading or glazing, and without heating.

A Norton Alundum grinding wheel, grain 46, grade J, in the illustration was proven to possess all these necessary qualities. The saving was decidedly worth while.

We would be pleased to advise further details and to consider your particular problem individually.

Milling Eight Transmission Covers At One Time

Machining Four Spur Gears Simultaneously—Producing Cluster Gear at High Speed—Method of Machining Piston—Milling Two Thousand Sad Irons Every Ten Hours—Brake Lever Fixture

By J. H. MOORE

THE AUTOMOTIVE industry has done much to advance the development of automatic machinery. Even a casual visitor to a modern automobile plant cannot help but be impressed when he sees the number and variety of automatics used. Skilled labor is dispensed with as much as possible, the machine, rather than the operator, doing the thinking. It is impossible to discuss all types of automatics in one article, and in the present instance we will confine the example of work produced, to one type of automatic lathe and one style of continuous milling machine.

The automatic lathe we are about to discuss is designed for the rapid production of duplicate parts in large quantities. The work is usually either held in a chuck, or mounted on an arbor between centres as in the case of an ordinary lathe. The drive clutch is then thrown in, and the feed worm lifted into position. Both feeds are thus started and continue until the side carriage trips the feed at a predetermined position. Quick return to starting point is taken care of, and the operator throws out the clutch, removes the finished work and completes the process all over again. With this automatic feature, one operator can run two or more machines depending upon the nature of the work produced.

Both the side and right angle carriages of the machine are arranged to carry multiple tools, the side carriages being used for turning diameters, while the right angle carriage is used for facing and slotting. Four or more tools can be used on each carriage at the same time, this feature of course, placing the tool on a high productive basis.

Various speeds and feeds are arranged for, and the feed for the right angle carriages is obtained through a drum driven by rack and pinion Any shape of cam can be mounted on this drum, making it possible to secure feeds on the rear head different to those provided by the feed gears for the turning head. With this brief description of the machine itself, we will pass on to Fig. 1 which shows a cluster gear machined in the following manner.

The first operation is to bore the centre hole, and face both outside ends. Two half-inch holes are then drilled in the face of the largest diameter to be used for driving purposes. The piece is

Figs. 1 to 5 through courtesy of Rockford Machine Co., Rockford, Ill. Figs. 6 to 8 by permission of Becker Milling Machine Co., Hyde Park, Boston, Mass.

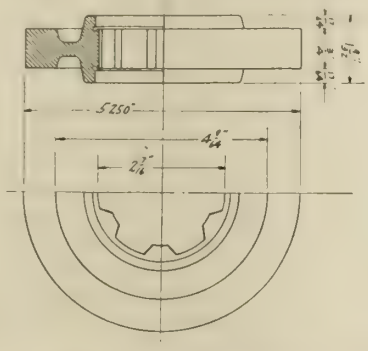

Fig. 3.—Details of spur gear.

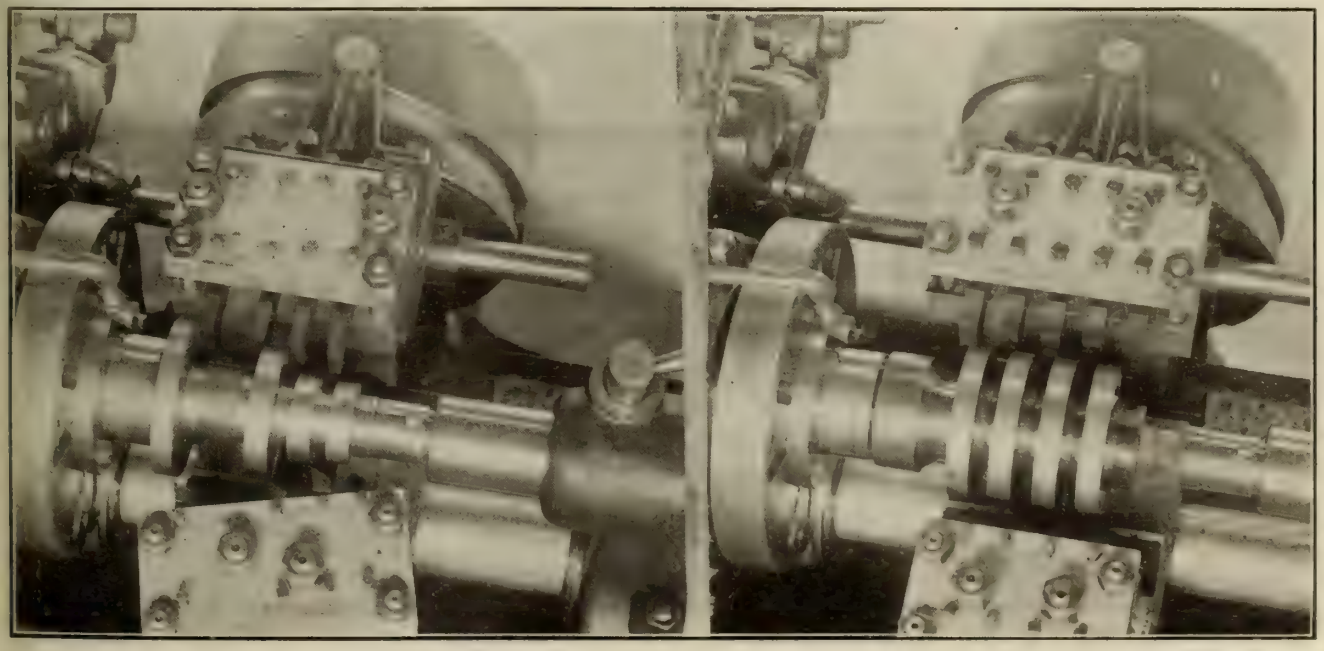

Fig. 2.—Left: Turning outside diameters of cluster gear.

Fig. 4.—Right: Four spur gears being machined at one time.

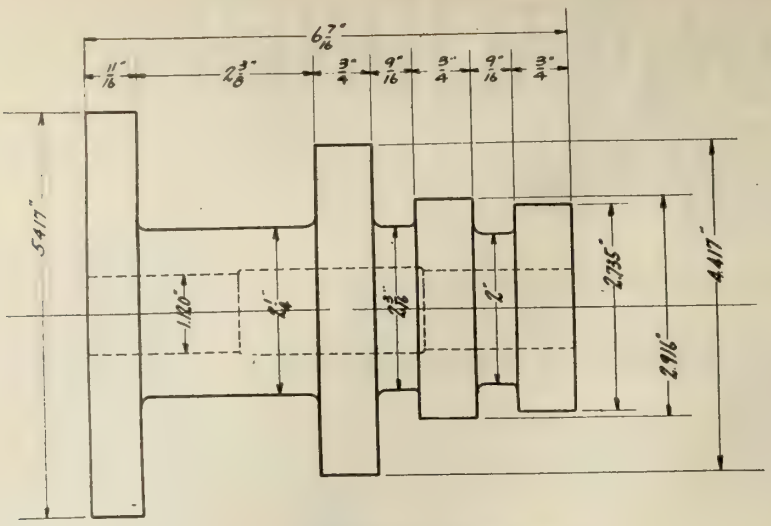

Fig. 1.—Line drawing of cluster gear.

next mounted on an arbor and placed in the lathe as shown at Fig. 2. The outside diameters are turned by four tools in the front carriage, while all sides are faced with tools in the rear carriages.

A special arbor is used on this work with a tapered end which fits into the taper hole of the spindle and the rear end is supported in a special fixture which fits into the tail stock spindle and is bronze bushed, this allowing the arbor to run in the bearing, instead of being supported on the regular center. This makes a more rigid job.

A ball bearing is placed between the rear end of the gear and the tail stock spindle thus avoiding any friction which might take place with the regular collar. The tail stock spindle is provided with a special lead screw, so that the spindle can be returned rapidly thus avoiding loss of time when changing gears. The cluster is finished in two operations, roughing and finishing, and the total production time for one machine is seven minutes. If an operator is handling two machines, the complete gear is made in less than four minutes.

Machine Gear Spurs

Fig. 3 shows a detail view of a spur gear, while Fig. 4 shows four of these gears being machined at one time. The parts are first bored, then the keyways broached and a special splined arbor is provided, this being of sufficient length to accommodate four gears with spacing collars at one time. The gears are finished in one operation, all facing and turning being done at the same time. Four gears are completed every three minutes with this set up.

Fig. 5 shows a sketch of a piston machined on this type of automatic lathe.

In completing these pistons they are first chucked from the inside, and the skirt end bored and faced. They are then taken to a drill press, mounted on a suitable fixture and a cross hole rough bored. They are next placed on the automatic lathe, rough turned, and the slots cut at the rate of forty-five per hour, one operator running two machines thus producing ninety pistons per hour. This type of machine is also adapted for the turning of cone pulleys, or any other work where turning and facing operations can be accomplished at the same time.

Milling Transmission Cover

Continuous milling has proved a very valuable production aid and since its innovation, many improvements have

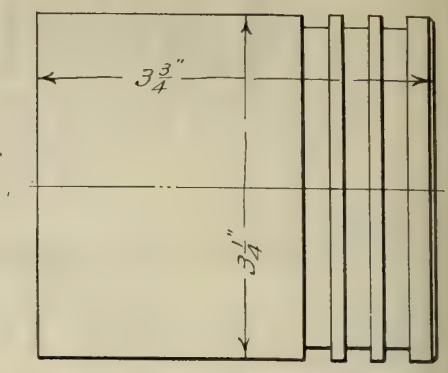

Fig. 5.—Details of machined piston.

taken place. We now have special machines for milling the ends of axles, cam shafts, etc., some of these being of the drum type. The work shown in this article however is completed on vertical spindle machines.

Fig. 6 shows a machine equipped to mill eight transmission case covers at one time. Four of these parts are placed in a position to have the large flat area milled, while the other four are set end up, the boss being milled as shown. This is a good example of careful fixture design and illustrates what can be done by a little thought. Note the simple method of clamping and how the vertical fixture clamps fit into the slot on the locating pin holder.

Fig. 7 shows an interesting shackle torsion fixture. Twenty-four parts are accommodated at one time, and it will be noted that four of the stations are left unfilled for clearness of view. The design of the clamps, how they are quickly released, etc, can be plainly noted in the photograph and attention is drawn to the slot in the bushing behind the clamp which keeps the clamps in proper alignment. A high production rate is obtained with this fixture.

Milling connecting rods by the continuous method is now common practice and the production rate in many cases has more than doubled since its adoption. When six, eight and twelve cylinder cars were developed it meant that more connecting rods were required

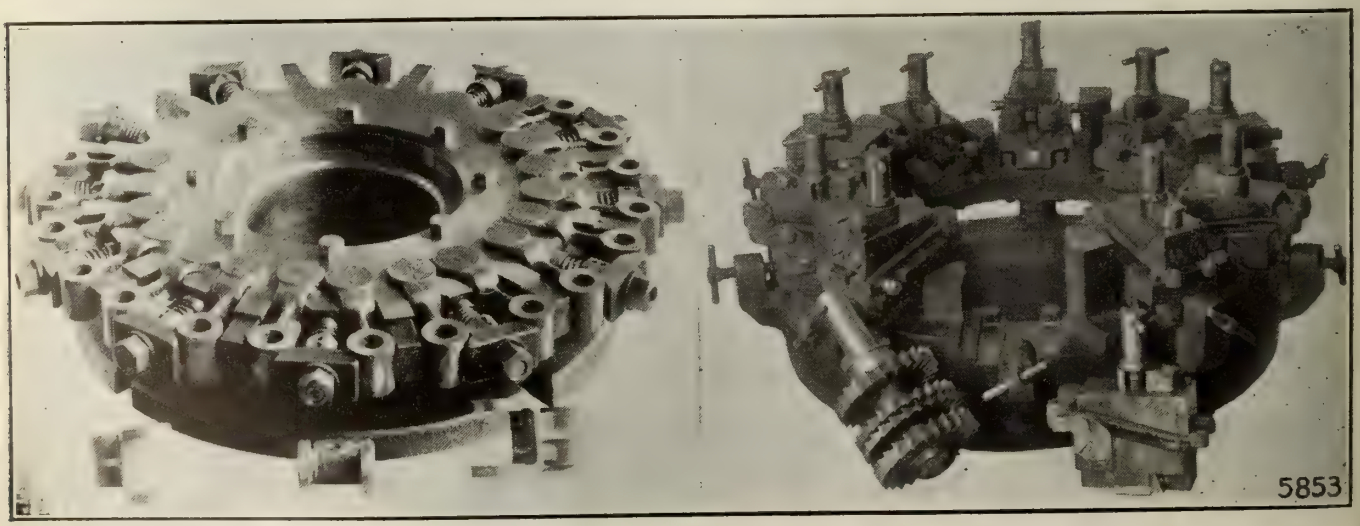

Fig. 7.—Left: Fixture for holding 24 shackle pieces.

Fig. 8.—Right: Fixture for holding brake levers.

every year and by placing these in special continuous milling fixtures, output naturally increased. For example a double spindle vertical miller, together with suitable fixture, can produce 13 in. rods at the rate of 45 per hour, while on smaller sizes, as high as 90 per hour can be completed. The number of rods held at one time varies from 12 to 20 and on the double spindle machines, both ends are finished simultaneously.

In the making of sad irons, a smooth surface must be obtained on the bottom. This is often accomplished by means of a vertical miller and on the type of machine we have already illustrated, two hundred of these irons have been milled per hour. The fixture used to secure this production held 14 parts at one time, in other words two thousand of these castings were completed every ten hours.

The milling of motor frames for automobile starters is another operation that lends itself admirably to continuous milling. On one fixture holding ten frames at one time, a production rate of 80 per hour was secured.

Milling spring seat caps is another good operation. These castings are made of malleable iron, and in a fixture holding twenty caps at one time, a production of 100 per hour or 900 per nine hour day was obtained.

In the manufacture of automobile starters it is necessary to machine both sides of the cover. This is the style of operation peculiarly suited to continuous milling, as long and tedious set ups are avoided. The irregular shape of the covers are well taken care of by a suitable fixture holding 14 pieces at once and in this case production was increased to 400 per ten hour day.

Considering a final example, refer to Fig. 8. The fixture shown is a continuous milling jig to accommodate hand brake levers. These are drop forgings and the operation is straddle milling. Four faces are machined in two operations. The production rate being 80 complete levers per hour.

It will be noticed that each jig is a unit in itself, although mounted in one circular block and that in one case, the small end of the lever is exposed, while in the other, the large end is toward the cutters. This, of course, explains why the cutters on machine arbor are spaced as shown. It means that production can be increased, set ups can be avoided and the levers completed rapidly in two operations.

In work of this nature, the design of the fixture is very important. To get the most out of a continuous milling machine, the fixtures must be made to reduce lost motion to a minimum. The operator should always be kept busy loading and unloading and speeds and feeds should be studied closely. Speed up the machine to the limit and make sure the cutters are of good steel. A case in point. In a certain automotive plant, name censored for obvious reasons, a continuous miller was being used to machine connecting rods. The production was disappointing and some felt the machine was not all it should be. In fact the changing to another method of machining was being contemplated. Eventually the firm decided to have one more try and they made the best cutter they knew how. As they felt the fixture was O. K. they left it alone, with the result that production was more than doubled. The cutter, not the machine, had been at fault. Therefore, make sure of the cutter and fixture used, the capacity of the operator, and the rapidity with which he receives his parts, before you blame the machine.

A 20-page booklet has been published by the Hydraulic Society, New York, entitled "Trade Standards in the Pump Industry." This work explains what is meant by trade pumps, plain fitted pumps, or brass fitted pumps; what is considered standard equipment for trade pump and what are considered extras; typical sizes of trade pumps are shown and definitions are given of terms used in the industry such as static head, total dynamic head, static suction lift, dynamic suction lift, etc. The booklet is recommended by the society as a guide to pump users.

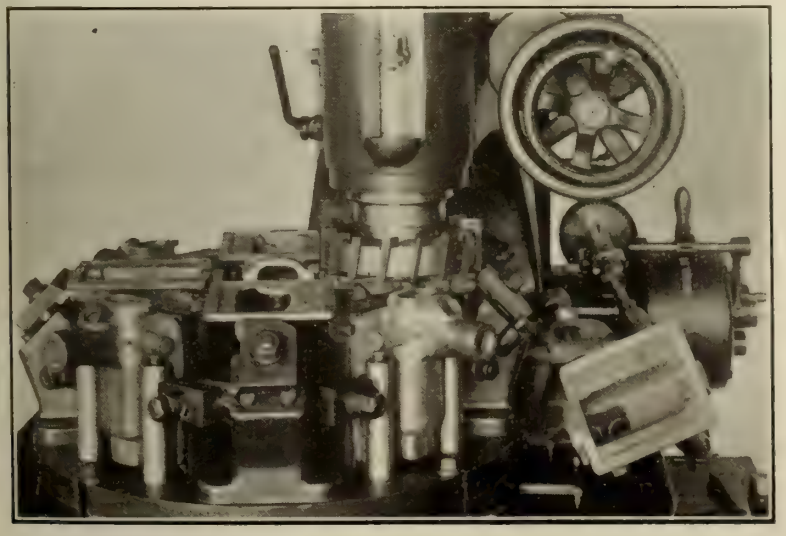

Fig. 6.—Machining eight transmission case covers.

NEW SHAFT COUPLING

An ingenious method of coupling shafts for power transmission has recently been devised by the Coventry Chain Co. of Coventry, England. It comprises a double chain, i.e., two chains side by side, which passes round toothed flanges on shafts which it is desired to couple. The coupling is readily made by a bolt passing through adjacent links connecting up the two ends of the chain in the usual way. The coupling has a very high factor of safety, it is perfectly balanced, being machined all over, and does not require any lubrication.

The facility for disconnecting the shafts will be apparent, and the method gives a large number of possible adjustments by which one shaft may be angularly set relative to the other through the medium of the teeth into which the rollers of the chain are fitted. Although this coupling is not designed to replace universal joints it is obvious that a measure of flexibility is obtained, and it is stated that the coupling can be used to couple shafts with a deviation in angular movements of two degrees.

Relative end movement between the two shafts is also provided for, limited to about 1-16th of the shaft diameter. A special application of this chain coupling is with regard to automobiles, particularly in such cases as that of the magneto shaft where angular adjustment is sometimes required and where a slight flexibility is considered advantageous to avoid transmission of small vibrations. The coupling is manufactured in fifteen sizes which have been completely standardized, the largest type being capable of transmitting 180 h.p. at 100 revolutions per minute.

ARTIFICIAL DAYLIGHT

One of the most interesting problems in illumination is to provide an artificial source of light which will exactly reproduce ordinary daylight. One way of obtaining the desired result is to filter the light of an electric or other lamp through special glasses, but a British inventor recently produced another form in which all the light is reflected from an umbrella shaped reflector on which patches of certain colours are painted. All the light used comes from this reflector and is modified by the colours to give a very exact imitation of daylight. An improved form of this artificial daylight apparatus has just been patented. The reflector consists of two layers of material perforated with holes so that a certain number of spots of the colours are exposed. Radial strips of another colour are placed over the perforated layers, the whole arrangement being mechanically strong and giving the correct areas of the various colours to provide artificial daylight.

E. M. Ashworth, manager of the Toronto Hydro-Electric System, is the new president of the Electric Club.

Mastering The Goggle Problem In Our Plant

Making Every Employee Wear Goggles as a Protecting Measure —Using a Sweat Pad as a Help in Hot Weather—Convincing the Men That it is to Their Advantage to Wear Goggles While at Work

By G. A. KUECHENMEISTER
Personal Manager of The Dominion Forge and Stamping Company.

"GEORGE wants to see you." That was the message I got one day while going through the shop. When I saw George, the superintendent, he told me that he wanted an order put up at once that all men in the hammer shops **must** wear goggles **all the time.** An order like that coming from the superintendent staggered me for a while but I finally "came to" and began to realize that the long hoped for event was about to happen.

Before writing the notice that was to make "safety history" in our shop, we discussed the matter thoroughly and came to several definite conclusions.

First, that we did not need a new order; that the rule in our book needed only to be enforced.

Second, that what had been done in the grinding department, i. e., allowing no man to work in that department without goggles, could be done in all the other departments.

Third, that no man ever began wearing glasses until he had been convinced that it was necessary for him to do so. We determined to provide the incentive and make it necessary for men to wear goggles.

Fourth, that knowing the dangers that the men were exposed to, it was our duty to take a firm stand and prevent the loss of eyes in our shop. With this in mind, we posted the following notice:

NOTICE

During the past few years the company has spent thousands of dollars installing many mechanical guards on machines and rebuilding the plant for the purpose of providing safe working conditions.

There are, however, many hazards that cannot be eliminated by mechanical guards and must be taken care of by the men.

Eye injuries can be stopped by wearing goggles. Many of the men now wear goggles **all the time** and rarely, if ever, get "foreign bodies" in their eyes.

The eye injury sustained by Theophile Tousignant on May 3rd would not have occurred had he been wearing goggles. It was only luck that has kept him from losing one or both eyes, and he says he has learned his lesson and will wear goggles from now on.

In order that this lesson be brought home to all of the men, and to henceforth prevent serious eye injuries, Rule No. 19 which reads as follows:

"GLASSES OR GOGGLES MUST BE WORN BY ALL EMPLOYEES WORKING AT EMERY OR OTHER GRINDING OR POLISHING WHEELS; WHILE CHIPPING STEEL. IRON OR CONCRETE, CUTTING OFF RIVETS, BABBITING, POURING MOLTEN METAL OR ANY OTHER OPERATION LIKELY TO CAUSE EYE INJURIES."

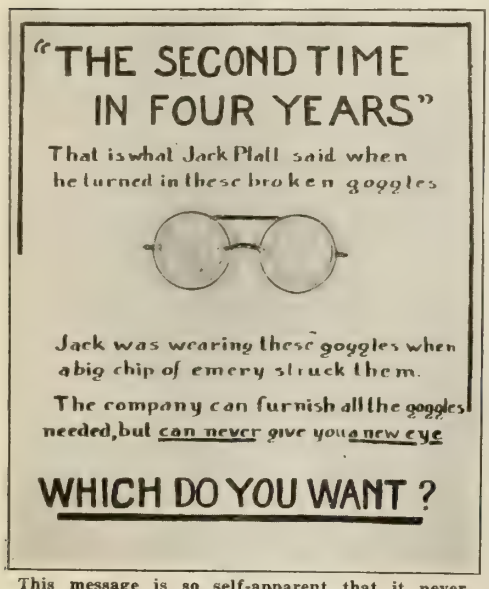
will be considered to mean that every man in the hammer departments must wear approved goggles or glasses **at all times,** and men in other departments must wear them as stated in the rule.

Goggles will be furnished free in the first-aid room as in the past and every man is requested to secure a pair at once.

Foremen will be responsible for the enforcement of this rule.

The notice was posted on the main bulletin board Saturday noon, and we waited anxiously to see what would happen when the men read it Monday morning.

The answer came quickly when the men saw the notice. It was "Huh, this should have been done a long time ago."



Of course, there were a few of the men who insisted they could not wear goggles but none of them said they would not. When these men complained to the foremen they found in several cases that the foremen were in the same fix; that they, the foremen, found wearing goggles very annoying and in some cases a real hardship until they became accustomed to them.

One of our best foremen faithfully began wearing large glasses the morning he read the order. He was complimented by the manager and replied that if the men had to wear them he would do the same thing. Three days later he came into the office and announced that if he had to continue wearing glasses he would have to quit his job. We laughed at him and told him that he would neither quit his job nor quit wearing glasses; that the order was not intended to force any man out of the shop and surely not him.

He insisted that it could not be done; that he was suffering from unbearable headaches and that he was through right there and then. We only smiled and asked if he knew of a good eye specialist. He said he had a friend who was an eye specialist. In five minutes we had the doctor on the phone and in an hour the foreman was on his way to the office.

That foreman came back in a few hours and told a story that made us wonder how many more like him we had in the plant. He told us that the doctor had proved to him beyond any possibility of doubt that it was his left eye that was causing the trouble. He said that the doctor had asked him when he had the left eye injured and that he had answered "fourteen years ago." According to the doctor this man should have been wearing glasses for the past ten years and it was only the goggle order that had forced him out into the open where he had to submit to an examination that showed a real need for immediate attention.

This man had a reputation for being irritable and peevish, and had to be

This message is so self-apparent that it never fails to get across.

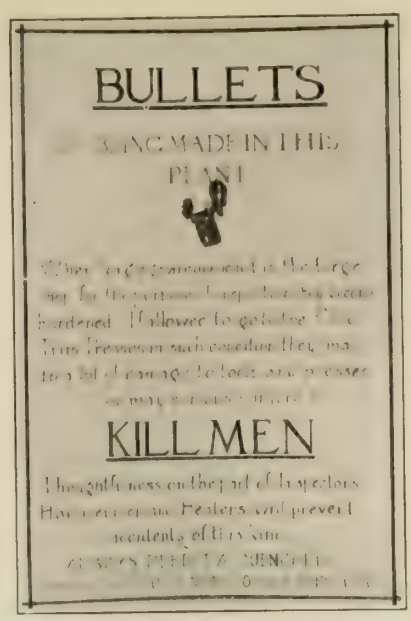
Another type of bulletin used to emphasize the message of safety.

handled with kid gloves. He very often refused to take part in social doings at night because he "wasn't feeling well" and he was considered quite a "crab." When that man had the proper glasses fitted to his eyes he was a changed man. Now he comes in and slaps you on the back, and is as jolly a character as there is in the plant.

We do not believe that a miracle was wrought in a day. We do believe, however, that our persistent efforts covering a number of years did at last bring results. Had we tried to put across an order of that kind without the preliminary work it might have resulted in a young riot.

It has been our aim to prove to the men that the goggles we provided, free of any charge, could be worn without undue discomfort, and that in every case where headaches were complained of the trouble was in the eye and not in the goggle.

We had proved to a dozen men that they not only needed to wear goggles in the shop all day, but that they needed to wear glasses with special lens **all the time.** We proved it by the simple method of taking them down town to our eye specialist, or one of their own selection, and having their eyes tested. In every case they were sent back to the plant with a prescription for a lens that corrected the defect found in the eye.



In those cases we then gave the man a goggle frame and had him have a lens made to fit the frame. We paid for the examination and the man paid for the lens. There was never any unwillingness to pay for the lens on the part of the man after we had paid to prove that he needed to wear glasses.

We have men who try to beat the game whenever they think they can get away with it. Those same men will beat the clock and break the rule against smoking in like manner, but they do not last long.

Not long ago a young man was called into the office and was told he was being let out for two reasons; i. e., for being caught without his goggles three times in two days and because he was producing just half of what other men could do on the same machine. Two very good reasons and of equal importance in the plant since the goggle order went into effect.

A colored boy came in the other day and cursed the goggles and vowed he could not and would not wear them any more. We laughed at him and jollied him, and he became serious and said he simply could not wear them because "they made him sweat." Nothing we could say would convince him. Solicitation about his losing one of his beautiful brown eyes only made him say that he did not care what happened to his eyes —he couldn't wear goggles.

After such a positive statement there was nothing to do but tell him that, although we were very sorry to know that he did not care whether he lost an eye or two, we would be sorry to hear about

it when it happened and that we were dead sure of one thing—that it would not be lost in our plant.

While going through the motions of getting his "clearance" papers so that he could get his pay in full, we incidentally handed him a broken, blue, glass eye and told him to take it; we told him we knew he would some day need it and we wanted to show him our hearts were in the right place and save him ten or twelve dollars. The old story worked. He is wearing goggles and says he needs no "sweat pad" because **he does not sweat!**

We feel that merely putting up an order that goggles must be worn will

Showing how the respiration pad fits over the forehead.

not instantly cause the men to madly scramble for goggles and faithfully wear them. It is too serious a matter to handle in such an abrupt manner. We have proved, to our own satisfaction, that men can be induced to wear goggles while at work and that an order compelling them to wear them all the time, after the preliminary work has been done, provides a good starting point for an intensive campaign. It takes the whole matter from a "do it if you like" affair and puts it in position where it can be handled as any other shop ruling that requires discipline to maintain.

C. O. Hurlbut, shoe manufacturers at St. Mary's, Ont., will erect a new shoe factory shortly. It is expected that the town will vote on guarantee bonds amounting to $20,000.

HOW TO LUBRICATE DRIVING CHAINS

WE HAVE read with interest your short article on page 68, Feb. 2 issue, on the subject of "Lubrication of Driving Chains," says H. A. Weston, of the Canadian Link Belt Co. "As manufacturers of roller chain for power transmission on trucks and tractors," continues Mr. Weston, "we have had considerable experience in the care and operation of these chains and believe that suggestions outlined in your article are good ones.

"We have also found that the use of a lubricant the grade of an extra heavy engine oil is superior in many cases to greases or graphite compounds, as an oil which will flow readily has a tendency to form a film around the bearing surfaces on the pins and bushings. The wear which takes place in a roller chain, and which allows the chain to become elongated takes place between the bushings and rollers, and although these parts are case-hardened a film of oil is necessary to reduce wear and prevent cutting and burning. A hard grease or graphite sometimes will not form this lubricating film.

"Among the large users of chain driven trucks and tractors we find that those who keep their chains in the best condition apply some sort of extra heavy engine oil to the chains with a brush every morning before leaving the garage. This fairly light oil will not retain grit to any great extent, and, flowing freely, it has a tendency to wash out the chains when in operation.

"We feel that the only really successful lubrication for roller chains is by the use of a tight casing, giving the chain an automatic oil bath and washing out any dirt which might accumulate and causing to be formed constantly the highly important film oil on the bearing parts."

EXPRESS GOODS SERVICE BY AIR

In spite of the depression in the world of aviation, the organisation of aeroplane services between London and the continent continues to develop. The lighting arrangements, which will enable regular flying at night to be carried on across the channel, have been completed, and several machines have been equipped with the necessary instruments for these night flights which will be carried out under practically all conditions of weather. What the British organisers are aiming at is a reliable and constant goods service between London and Paris, so that parcels consigned from the provinces to London or to Paris on one day will be delivered at the other capital on the following morning. As soon as this regular service is established it is expected to be largely patronised owing to the fact that the aeroplane can beat the ordinary means of transport by many hours.

Careful Tool Set-up Assures Better Production

Automatic Machines Should be Kept in Good Condition—Operator Must See That All Settings Are Properly Made Before Starting Machine—Effective Feeding Mechanism Reduces Unproductive Time

By DONALD A. HAMPSON

THE AUTOMATIC screw machine is the oldest and best known of the automatic machine tools. Only a few weeks ago occurred the death of the inventor of the Spencer automatic, which is the prototype of the single spindle automatic now in widespread use, the exception being the Brown and Sharpe machine.

There are full automatic millers, drills, and turning machines, but these are employed mostly in great production plants such as those in the automatic field. Even these are seldom "full automatic" as an attendant must load and unload each work piece. A few classes of work can be loaded into a hopper or magazine and then the machine really becomes automatic.

But the automatic screw machine has become so much of a necessity in manufacturing, machine and repair shops and in general manufacturing plants, that it must be included with the lathe and the drill as all-necessary machine tools. Practically every small plant has one or more automatics; in pocket knife shops, they may be seen making little shoulder pins—in corset factories, they are quietly at work dropping off tiny studs; while the general machine shop finds them a paying investment for so small an order as 500 pieces.

It is to be admitted that some of the work turned out in private plants is not as well done as that from specialists in screw machine work, nor is it always as economical, but there is the undeniable advantage of being able to get what you want from it, of having the work right under your own roof, and of being able to make changes at any time. The latter is of much value—after a few pieces are turned out, an assembly can be made and if this shows that more or less fit is required and that some minor change will expedite further work, it i a short matter to adjust the automatic to suit.

Quality and quantity of work depend on three factors, i. e., the condition of the machine, ability of the operator, and skilfulness of the overhead, the latter, including the supervisor, tool designer, and planning department. Thousands of machines are in use that are not new but which are doing the work or can be made to do good work by the replacement of a few vital parts at a nominal cost. In shops where but a few automatics are employed, the operator is frequently his own set-up man or he does the setting up under the direction of a foreman or a machinist of experience. The present article should prove of particular interest to men in such plants—men who have to work out their own salvation, never visited by a road man from the automatic plants, often working hundreds of miles from another shop or another man in the same line.

Feeding the Stock

Setting up is the most important part of screw machine work. It includes the proper lay-out of tools, sizing the cuts, starting up, and various preliminaries. A good careful set-up assures production, even if ordinary intelligent help runs the machine afterwards. Selection and preparation of the stock helps wonderfully. It pays to have the bars chamfered at both ends: if this is not done, much time is spent in hammering the two ends through the shells and very likely the latter will get broken as bar stock is sheared to length and thus is left with a swelled or burred end. In buying stock from the mill, it is possible to get the bars chamfered on one end at an advance of only a few cents per 100 lbs.—it pays to do this for such stock is cut off in a cutting-off machine which leaves both ends in good shape, beside one with a bevel.

Crooked bars produce innumerable delays through interference with feeding. If the crooked bars cannot be used in some other department, it is best to throw them out altogether or else to cut out the bent sections, using the rest when a lot of short bars are being worked up. Cold drawn stock is superior to hot drawn for small work and will save its additional cost in time saved on feed troubles.

Feed shells, or feed "fingers", lose their tension after a time and need to be sprung together with wire, heated, and re-tempered in the closed up position. When stock up to the machine's capacity is being run, there is apt to be trouble in feeding the bars because the shell is not strong enough. Fig. 1 shows how this weakness may be overcome. A thin band of steel is slipped over the shell as shown and in its position it stiffens because the effective length of the slot is decreased.

Increasing Machine Range

Fig. 2 shows how small stock can be handled in a large machine. Some machines are not regularly supplied with master collets and shells and interchangeable pads to go with them. If a job comes up suddenly or but a small quantity of some odd size is required, it may be advisable to resort to shop made equipment and this can be produced very reasonably as shown. A threaded bushing is made for the front end of the feed tube and in it is screwed a new shell which is simply produced from a straight piece of tool steel. The small collet is turned with a narrow hub at one end to fit inside the rear of the master collet or any suitable collet that is large enough; the rest of its length is straight and when it is split and expanded, it functions through the medium of the larger collet. The writer has turned out many thousands of pieces with parts as illustrated and found them extremely satisfactory.

Regardless of circumstances and notions, it is bad practice to alter machines from the way they are built. And yet two or three cases have come to notice where better results were secured by rethreading the feeding tube left hand and making the shells left to fit. All these cases were in connection with machines having an "increased to" capacity which of course, necessitated the use of a thin walled feed tube and rather light sectioned collet feed shell. The fine thread that had to be used then to join the two pieces was none too substantial and soon

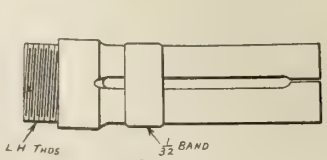


Fig. 1

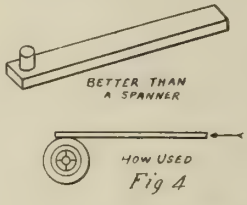

Fig 4

Fig. 2.—Increasing range of machine.
Fig. 4.—Device used in removing tight chucks.

troubles with the shell unscrewing would occur. This unscrewing of shells puzzles operators until they consider that in most machines there is a period during feeding when the feed tube stands still and during which time the surrounding members may be in frictional contact with the shell and have a tendency to unscrew the latter as they are turning right handed. Where the threads and the shoulders are too frail to withstand much pressure, left hand threads will prevent unscrewing troubles.

An aid to feeding small stock in a large machine is a bushing in the rear end of the feed tube. For instance, suppose ⅞ in. bars are being run in a 2½ in. machine, which is by no means the extreme that is met with in small screw machine departments. After the bar leaves the stock tube there is an overhanging piece several feet long and weighing from six to ten pounds that is supported by the collet and shell at the far end; the leverage is too great for everyday conditions and naturally the feed does not work well. Place a bushing somewhere inside the feed tube and the trouble will be eliminated—bushing should have a hole 1/16 in. larger than the stock.

Provide Plenty of Room

There are also many details to be attended to in setting up and in operating automatics that access to all parts of the machines should be made easy. It does not pay to crowd the machines in a department. Ends and back of machines should be as accessible as the front and there should be room for the workman to squat down without bumping himself. An operator or set up man who has to work all day, taking little mincing steps ("one-stepping") about the machines, squeezing between bars and machines, and ducking under stock tubes, and so forth is tired at quitting time and his work for the last couple of hours has not been of the most productive kind. Hence, it is money saved to give automatics plenty of room, even at the expense of crowding other types of tools.

Silencing Gears

Noise in a plant may give it a "prosperity hustle" tone to the visitor but it is more or less wearing to the nerves of sensitive workmen. Very little has been done to reduce the noise from automatics; analyzed, this noise consists of the sound of running gears and belts—which cannot be lessened much—and of the rattle of bars in the stock tubes—which can be toned down considerably if tried. Multiple spindle machines are the most prolific noise makers. It is customary to supply the stock tubes considerably larger than the maximum capacity of the machine—for instance, on a ¾ in. Acme automatic, the stock tubes will admit bars nearly twice that size; this makes for easy feeding but it adds to the jingle.

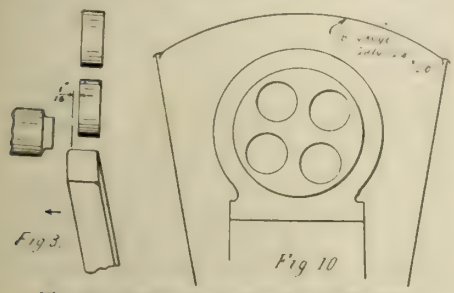

Fig. 10.—Guard for preventing oil splash.
Fig. 3.—Relation of rollers to cutting tool.

Smaller stock tubes will help some but not enough to justify a change—the metal to metal contact is there just the same. It seems to be considered better to put up with the noise than resort to fussy means to reduce it. In special cases, however, much can be done to quiet an automatic department. One superintendent who was willing to go to elaborate means took practically all the noise out of his rapidly revolving bars. His machines were working month after month on the same size bars (about 1 in.) and he put bushings in each end of his stock tubes, about an eighth larger than the bars. Then at each end of each tube was a thick felt ring held between caps as in the best automobile practice.

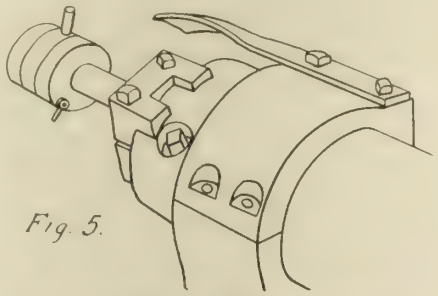

Fig. 5.—Keeping die head in position.

The felts had to be renewed from time to time but they effectually pocketed the noise. They also served as wipers for the bars.

The writer once had several automatics running on C. D. S. bars of 9/16 and 5/8 size. The machines were set up and and left from year to year on these same sizes. It was thus possible to do something with the noise and distribute the cost over a vast amount of work. Cheap ball bearings—of the so-called "commercial type"—were fitted into each end of the stock tubes. Their bore was 1/16 in. over the bar sizes and their cost for a four spindle machine less than $2. With them in place and the bars revolving at about 1000 r. p. m., a four spindle machine emitted hardly more than a purr. Three months of steady running was the minimum life of the bearings with a maximum of quiet.

Regulating Feed

To have the stock feed regularly and be held so there is no slipping under the various cuts is to relieve the operator of half of his troubles. The successful operator thinks ahead of his machines and by so doing increases his production immensely. When bars cut without slipping back but do not feed uniformly, it is evident that there is a drag on the bars somewhere or that the feed shell is loose or weak or that the collet does not open far enough—the operator knows that the trouble is somewhere in the head-stock assembly and, by checking one unit at a time, he remedies the trouble speedily.

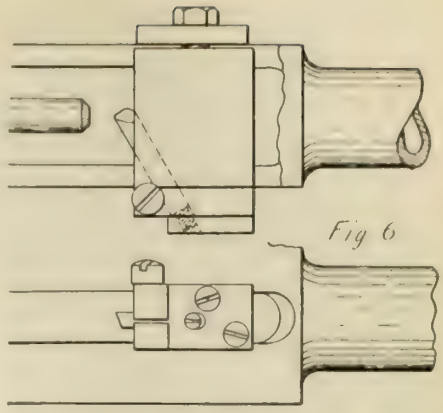

Fig. 6.—Pointing ends of shafts.

On the other hand, if the bars feed all right but push back when the turret tools are working, the indications point more strongly to dull or improperly set tools than to lack of grip. Fig. 3 shows in development a detail of the common turning tool with roller stock supports which many operators fail to grasp. Rollers must either precede the tool and ride on the original far diameter or they must be set far enough in the rear to escape positively any part of the cut but the newly milled size. If the rollers ride upon any part of the reduction but these two, they are just wearing their way along, because rollers cannot cut. The position shown is 1/16 in. to the rear of the desired diameter, which is none too much for clearance, tool wear, and possible slippage.

A source of trouble results from rehardening shells and collets and from shop made parts. Unless the contract faces of these parts are glass hard, they gather small particles of steel from the bars as shoved through and these same particles become "diggers" that scratch the bar and retard its free feeding. Longitudinal scratches on the bars themselves are the tell-tales of this trouble. Sometimes these impediments are so hard that they have to be ground or stoned to remove. Small in themselves, they give considerable trouble when there is only a small allowance for opening and closing in the gripping members.

Chips entering the slots in the collets work themselves between the outside and the nose piece, fill up the slots, and sometimes get farther back to the feed. Some operators fill the slots with rubber—and this works well for a time but in the long run it is far better not to tinker but rather to take out the chuck parts, say once a week, and rinse them in kerosene. The same is true of the spindle bore, the chuck closing tube, and the feed tube; an occasional dissecting and washing will free up these snugly assembled parts and work wonders with feeding.

Setting Up

Excepting very long runs, the cost of setting up is a major item in the cost of a given part. Anything which will

maintain that set-up intact is important. And nothing will completely derange the entire set-up quicker than a stoppage of the oil or coolant. On a job that is permanently set up, absence of pipe fittings is helpful. Where it can be done, as in the case of most single spindle machines, the writer prefers to go to the expense of a special piping outfit built entirely of bent pipes. Screens or not, chips will get into the pump and be carried into the delivery line, there to lodge in elbows and valves and necessitating cleaning out every so often. Practically all single spindle jobs can be arranged with a single piece of pipe or, at most, two pieces with one elbow and one cap. A valve in the overflow is all that is necessary to regulate the supply on the tools—and even an overflow line from the pump may be omitted. Any executive, who knows how attendants are given to fussing with a maze of pipes and valves in the oil line, and how much a cessation of supply costs, will bless the bent pipe system.

Careful Planning Needed

The cost of screw machine products in any factory "making their own" may be considerably reduced by careful planning. Suppose, for example, that there are five automatics in the department and that each machine must supply approximately 10,000 pieces each of fifteen different parts per year. That means seventy-five different set-ups in the year, which will keep one man fairly busy. Critics will immediately arise to say that a set-up is a matter of but a few hours time. However, the wise ones will agree with the author when he says that under average conditions very few machines are changed from one job to another and are ready to run without further testing out in a day's time—the simplest of jobs or a change in length can be made in less, while complicated parts will take much more. And so it is that the planning of this kind of work demands good judgment and broad experience.

First, the number of parts or designs should be studied in their relation to the sizes and styles of the automatics. It may be found that some designs could be produced so much cheaper on another machine that it will pay to buy a new one and get rid of the one which did the work so slowly with frail tools working beyond their range. Secondly, the parts should be apportioned to the different machines according to their capacity and to the demands of the assembling department so there will be no delay in subsequent operations. Thirdly, great quantities of parts should be made at one setting—and this is especially true of those which are hard to set up because of the number of tools involved and intricacy of shape. Any such part which will be used year after year should be made in, say, five year lots. Where quantities such as have been named are used yearly, the saving by this practice will often, in effect, supply two years' parts free. Fourthly, the work should be so apportioned that parts of similar design follow each other on the same machine in order that as much as possible of a previous set-up may be utilized.

The first year that this system is followed will be the most trying. Some delays will occur. At times, additional equipment may seem necessary. But all the time the unit cost will be going down. The second year there will be no hitch. In all probability, the work will be going through so smoothly that it will be possible to get it all out on four machines instead of five and then it is possible to have one machine in reserve—this had better be the most universal, the one most readily changed, which can then be held in readiness for those inevitable specials that come up and for setting up in emergencies.

Get More Out of Belts

Motor driven is an ideal arrangement for automatics but the plant that has belt driven machines only has no cause for regret. Some work demands belt driven machines in order to get the required speed and direction changes for particular work. On the older machines, and some of the later models too, the pulleys for these belt-shifting drives are straight face. Hard pulling with a straight faced pulley always causes the belt to slip sideways and this side movement causes wear on the edge of the belt, especially at joints. If these pulleys are crowned, the belts will shift fully as well and, moreover, wear from the forks is almost entirely prevented. The belts pull better on crowned pulleys.

During the war, the price of leather belting rose to such a high level that manufactured belts of many kinds came into extensive use. No one claimed that these woven and impregnated belts were as efficient as leather—they are not—but the price was so much lower that other considerations were overlooked. A good many plants will continue to use these belts. The ordinary screw machine fork is hard on manufactured belts; abrasion starts at the joints and unraveling follows, with loosening of the plies, and then the joint-fastening gives way. Meanwhile both edges have suffered throughout their entire length from constant crowding of the forks. Crowned pulleys are the salvation of belts in this application. A kink practised on these belts with marked success was to dip the ends in glue, leaving the work of making a joint until the next morning—the several ills grouped under the name of unraveling were largely reduced by this practice and a good deal of time saved.

Setting up For Threading

Screw machine jobs may be divided into two great classes—those with threads and those without. The former are more complicated and more interesting. Plain pieces can be made faster than threaded ones; not that threading is a slow process—for it is not, it is usually the fastest one and on multiple spindle machines it is done while other tools are performing slower operations—but because the nature and exactness of threads and thread tools involve more fitting, adjustments, breakage, and "hang-ups" and all these cut into the production rate.

Setting up for a threading job involves more work whether it is an internal or an external thread, cut or rolled. When setting-up for a threading job, the best plan is to do everything else first—get the machine running and making proper dimensions at full speed—and then apply the threading tools. Time will be saved by so doing and repetition of other work. This plan, naturally, presupposes that sufficient time and ample cam space have been allowed for or laid out.

A skillful man can save a good deal of money in a threading set-up. He will carefully measure every part concerned and every movement. He will set the cam or the dogs to give a little less travel than may be required, in order that the tap may not strike the bottom of a hole or dies wedge against a shoulder. Many men—far too many—will disregard these simple things and, putting in a new tap or set of chasers, will smash the outfit first time around. The same men will run a tap in a small hole and force dies over a blank much too large. After they have caused this wreckage, they measure things up and come out all right the second time. There is absolutely no excuse for breaking anything the first time; the skillful man (which is the same thing as saying the "thoughtful man") puts in an old tap and uses old chasers first off, even though he knows he is on the safe side. Such a man is highly valuable.

Care of Machines

When a job has been set up and dried out, it is not quite ready to be turned over to operator. Every bolt and screw ought to be gone over systematically first and tightened up—tried, at least. Half an hour spent in this will save hours later in rebuilding the set-up. A few minutes spent every day on bolts and screws is also time well spent. Automatics run so fast that a loosened screw can do hours of damage in a very few seconds.

The Acme screw machine is the most universally used of the four-spindle machines. Its features are therefore known to a legion of machinists. Because of the number of bars and of tool positions, the operator and the set-up man cannot see everything from the operating side. Many times he would like to be able to feed the machine by hand while watching the work in third and fourth positions. To enable him to do this, the author has made a connection on the rear so that the hand crank may be applied. In addition, a sheet steel guard has been put over the revolving ends of the turret spindles so that a man, in reaching over to apply the power is in no danger of getting his arm caught. These two little additions have saved their cost a hundred times over.

Someone has said in connection with the operation of Acme automatics, "Watch the cutting off tool and you're all right." There is a world of truth in that unstudied phrase.

(To be continued)

Selection of Doctor *Most* Important Matter

Various Questions Under Discussion at Present Regarding Workmen's Compensation—Should Employees Contribute to Insurance Premiums?—Better Statistical Methods Should be Adopted—Individual Experiences Would be Valuable

HOW many realize that no less a sum that $162,858,091.20 has been estimated to represent the value of product loss by one year's cripples in the Province of Ontario for their life time, while the total wage loss of these cripples for the same period has been estimated at $32,190,400.00? It is only by such figures that the full significance of this economic waste can be properly appreciated, remarks our informant who has made a close study of the situation.

The Ontario Workmen's Compensation Board says that since the present Act came into effect seven years ago, 271,807 claims have been dealt with and $27,947,655.45 has been awarded in compensation and medical aid benefits. Nearly 500 cheques are despatched daily carrying support and relief to the recipients. Cases are settled promptly without litigation or expense to either the employers or beneficiaries. The employer is immune from action in the courts of the Province and more than ninety-eight out of every one hundred dollars that is paid for compensation goes directly into the hands of the injured workmen or their dependents. The rates of assessment in general are not high in comparison with those in other places.

The principle of State controlled Compensation Boards is undoubtedly sound. It eliminates litigation, particularly when one considers that by method of private insurance as much as 40 to 60 per cent. of the premiums paid by employers is absorbed in expenses and profits, while in Ontario less than 2 per cent of the assessment paid by employers goes toward expenses. The Joint Safety Convention held at the King Edward Hotel, Toronto on April 4th and 5th went a long way toward bringing to light certain facts which probably had been a matter of conjecture or perhaps ignored altogether. Following are some interesting facts. The particular items under discussion at the present time are:—Contributory insurance by employees; exclusion of clerical staff; medical matters; contractors and statistical information. We will deal with these in order named.

Contributory Insurance by employees

If one pays insurance premiums it is because something is expected in return. I believe this would increase malingering. It is felt that a fair compensation should be paid by the company, unless accident is due to deliberate carelessness and disobedience of shop rules, in which case employee should not receive any compensation unless accident of a very serious nature when special consideration should be given. The act provides that no compensation be paid to injured in the event of wilful misconduct, and this should be strictly enforced by the board.

Another feature about contributory insurance is that it would entail a great deal of clerical work collecting the premiums. For instance, supposing an employer's rate per $100.00 is $1.50 on the maximum wage of $2,000 the assessment would be $30.00 per year. It has been suggested that the employee pay 10 per cent. of this. This would mean a contribution of $3.00 per year or 25c per month. Supposing a firm employed 1,000 employees, this would mean $1,500.-00, deduct from this the cost of clerical work, then figure out whether the end justifies the means.

Exclusion of Clerical Staff

From a group standpoint the inclusion of clerical staff has no bearing on the ultimate result. In other words, it simply means that the assessment is raised and the rate is lowered. A firm having a large amount included for clerical staff would be reimbursed on the merit rating system by the fact of the low accident cost, but only up to 30 per cent. The firm without a large clerical staff would have the advantage of not paying out the orginal assessment. The object of the board in not making any exclusions, we are told, is due to their inability to properly check up those that should be excluded and included.

It is neither just nor equitable to employers, and there would appear to be no justification for assessments being levied on wages of clerks working in general and branch offices remotely situated from the works simply to suit an auditor's convenience in checking. The speaker who termed this "all bosh," at the safety convention, was pretty nearly correct, in fact, it is downright preposterous that a board should have the power to cause such absurd legislation to be effected.

Medical Matters

Too much importance cannot be attached to the selection of efficient doctors. While it is not the intention to pass reflection on medical practitioners, it would seem to be a tendency for some doctors to prolong period of recovery in order to receive medical fees. This means additional expense to the employer in two ways—medical fees and unnecessary compensation. Where practicable the company should select its own doctor, pay him a certain amount per year, based on what has been paid by the compensation board for medical fees for a period of years, arrange with doctor to turn over the cheques received from the board to the company. His only interest then would be to get the men back to work, and in our opinion this would be the most effective way of curtailing any malingering which might exist.

Furthermore, it might be added that the amount of medical fees paid, compared with compensation payments, ranges anywhere from 10 to 90 per cent. In other words for every $100.00 of compensation paid, it has been established that the doctor has received as high as $90.00.

Contractors

According to an amendment to the act, employers are made responsible for the proper reporting of pay roll of employees of any contractors working on their premises. In the event of such employees having an accident while on such premises, and the contractor not having made a report to the board, the compensation for such accident is charged to the manufacturer employing the contractor. In other words an employer who complies with the regulations of the law is made responsible for those who do not.

Statistical Information

It must be realized that the workmen's compensation board is appointed for the proper administration of the act. Its business is to pay compensation. but we must also realize that in the formation of that act, provision was made for the organization of accident prevention associations, the cost of which is borne by the board and paid for by the various industries.

To these safety associations the board hands out data for every accident which is reported. It furthermore supplies these associations with the net assessments and costs for various classes and groups. The pay roll being obtained, the cost rate of accidents per $100.00 of pay roll can be ascertained for the group from which individual experience can be compared.

If all employers in a group were to supply the cost of accidents and rate to Mr. Morley, manager of the Industrial Accident Prevention Association, he could no doubt, compile and publish a comparative exhibit showing the cost rates for the respective employers, so that all members of that group might ascertain their respective status.

Unfortunately the cost figures referred to, which are supplied the Industrial Accident Prevention Association by the Board, may be given somewhat late to be of value. For instance 1920 figures were only provided, we believe, in 1922. What might possibly prove of

better value would be for the Industrial Accident Prevention Association to establish a statistical department whose function would be to tabulate and analyze reports they receive daily from the Board. A standard unit of measure should be adopted so that comparisons could be made on a basis representing similar conditions. Frequency rates should be expressed in terms of 300 day workers, severity rates in terms of time lost to time worked, with an estimated time loss of man power by death and permanent disability.

The publication and distribution of monthly reports giving the above information would undoubtedly create a competitive spirit between members of the group, and we believe would tend to materially reduce compensation costs. Mr. Morley has made a great many improvements since he was made general manager of the Industrial Accident Prevention Association less than one year ago, and it is safe to assume that this need for statistical data has received some consideration at his hands. It is a big undertaking and one which would naturally involve some expense.

Incidentally, there would appear to be no reason why the workmen's compensation board should not publish individual experience. These figures must of necessity be compiled for merit rating purposes and with a little more effort a classified report might easily be compiled and published. In conclusion, the writer was interested to note that mention was made by several speakers, of the play "Fixing the Responsibility for an Accident" which was staged by three Hamilton firms—The International Harvester Co., The Canadian Westinghouse Co. and the Steel Company of Canada.

The object of this play was to impress upon the employer the importance of properly training new employees. The first act depicts a modern shop with an up-to-date foreman who is courteous to his men and is anxious for their safety. The second acts depicts an old timer who is a foreman having no regard for "Safety First" principles. On the contrary he bullies his men and even the loss of an eye seems to have no special effect on him. In the third act the responsibility for this accident is placed with the final discharge of the foreman.

It has been admitted that no amount of talking or writing by the Ontario Safety League or others could bring home with more telling effect the object lesson contained in this play. These performances were given at the Memorial School, Hamilton, Massey Hall, Toronto, and the Cathedral Lyceum, Hamilton, with full houses at every performance. This was given under the auspices of the Hamilton Chamber of Commerce and the Ontario Safety League. The fact that such firms as those mentioned see fit to allow their employees full time while taking part in these performances is admittedly an indication that they at least recognize that accident prevention is a universal problem.

New Design of Radial Drill

IN THE operation of machine tools an item of extreme importance is the minimizing of unproductive time. To obtain the maximum efficiency from the operator it is necessary to place control levers within easy reach of his normal position when operating the machine.

Another essential factor is to incorporate features that will offset any possible neglect or oversight on the part of the workman to keep all functional parts well lubricated.

On the construction of the 4 ft. radial drill, here shown, special attention has been given by the builders, The Canadian Machinery Corporation, to two important considerations in the operation of machines of this type. First, the time wasted moving around that has been necessary in order to make adjustments for speeds and feeds, and secondly, the lack of power in most drills on slow speeds when the greatest power is required. To overcome the former, the carriage has been so designed that all contro's are centralized under the operater's hand. Gear boxes and countershafts are eliminated, all the speed changes being obtained by the manipulation of four levers through seventeen gears only, which are of nickel chrome steel, heat treated and running in a bath of oil. Thirty-six speeds are thus obtained without the operator leaving his position to shift a belt or adjust a detached gear box.

Ample Driving Power

To secure ample power, the initial speed of the transmission is maintained until after passing through the frictions in the reversing attachment, so that the speed in the frictions is exactly the same whether working at high or low speed. In many drills, this has been a weak point, for with low speed in the frictions, much less power is transmitted, causing slipping of the frictions.

Particular attention has been paid to the oiling system, and a central reservoir has been provided, thus eliminating the danger of the workman missing an oil hole. A circulating system of lubrication is maintained on the rear of the carriage and a large reservoir on the top of the speed changing gear box supplies oil to the bearings and transmission gears, and after performing its mission, is pumped back to the reservoir.

New design of radial drill.

It is a well known fact that under conditions of large "labor turnover" firms spending time and money on safety education usually result in some competitor deriving the benefit and it is hoped that such organizations as the Industrial Accident Prevention Association and the Ontario Safety League may see their way clear to promote such enterprises.

Correct Understanding of Mechanical Views

Mechanics Should Be Able to Read Drawings—Projection of Surfaces—Third Angle Method Generally Used—Transparent Box Simplifies Instruction

By JOHN HOMEWOOD

IF the projection of views was correctly understood among draftsmen and machinists, the draftsman would not be looked upon by a great majority of mechanics as one who delighted in putting puzzles upon paper. It is just as important for the man reading the blueprint to understand the fundamentals of projection as it is for him to know his multiplication tables in order to do division. The majority of mechanics have, in the past, acquired the art of reading drawings strictly from experience gained from each succeeding drawing that they came in contact with.

That experience may have covered a period of years, among which a great many drawings have come within their reach that were made by draftsmen who did not know their business when it came to giving the proper projection. It is surprising to know that a great percentage of men now in industry do not know the difference between third angle and first angle projection. This often results in spoiled work and great loss of time. I see no reason why a mechanic, when he is hired, should not be put through a short examination that would determine whether he does or does not understand the views on a drawing and their relation to each other.

There are hundreds of text books that cover the fundamentals of mechanical drawing, but there are very few that go into the elements sufficiently to give a practical man the information he wants in his own terms of understanding. While the following is widely known among draftsmen in general, as well as a great number of mechanics, it is incumbent upon the writer to plead for pardon from the "wiseacres" for bringing the subject up again. If it will be the means of making one man see the daylight in reading blueprints, it will have fulfilled its mission.

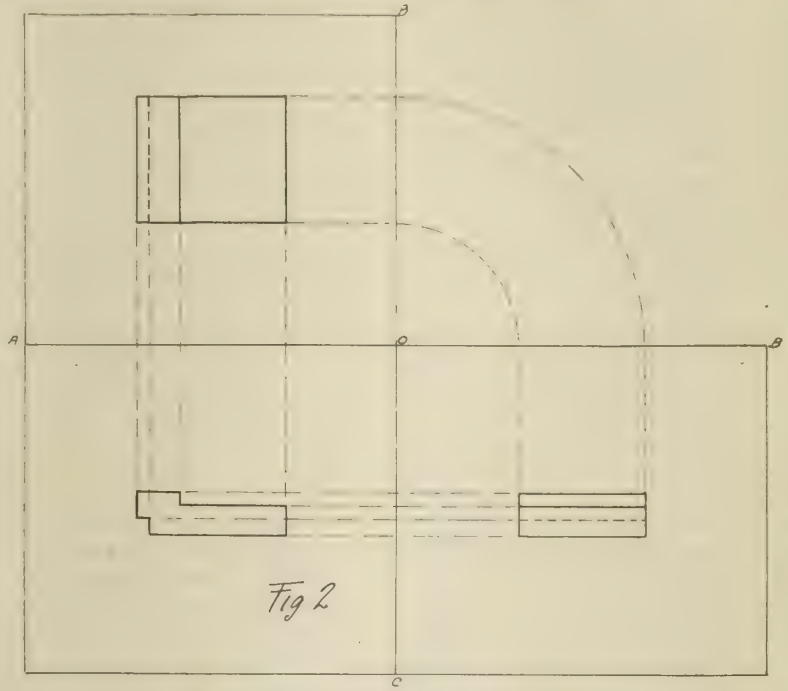

Fig. 2.—Surfaces projected on drawing board.

The type of drawing used in mechanical work is the art of representing objects that are to be made, by showing them in one or more views. The relation of these views to each other are governed by the rules covering Orthographic Projection. There are two kinds of Orthographic Projection; they are known as first angle and third angle. In this country we use the third angle projection. The first angle projection is used in some foreign countries and is also adopted in a few schools here simply to make the art of learning projection easier, by having the object revolve in one angle of 90 deg. If the object represented on the blueprint could be pictured as being within an imaginary box surrounding it, and its image transferred to the face of the box, and the box developed to be on one plane, the object will be represented in third angle projection.

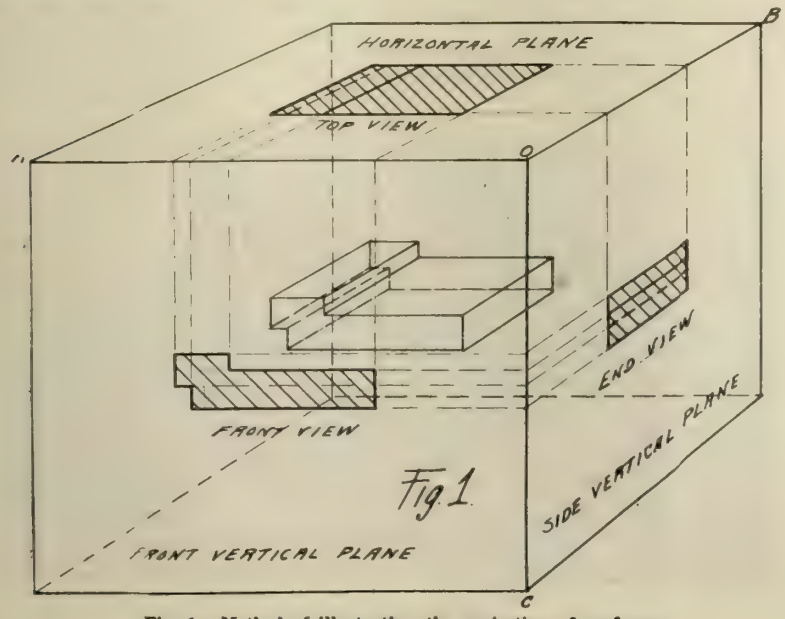

Fig. 1.—Method of illustrating the projection of surfaces.

In Figure 1 is shown, in perspective, a box constructed in transparent material. The top is hinged on the corner "AO," the side to the right is hinged on the corner "OC." This box is made to open on the top and end by swinging on the front side. The top is known as the horizontal plane; the front is the front vertical plane and the side is the side vertical plane.

The horizontal plane revolves on its axis "AO" which is known as the horizontal axis.

The side vertical plane revolves on its axis, which is known as the vertical axis.

This box referred to is primarily only imaginary, upon which the views of the

Gears Classified By Shaft Arrangement

Study of the Worm Wheel, Helical, Spiral and Skew Type — Peculiarities of the Hindley Worm—Method of Hobbing Teeth—Tangential Feed System.

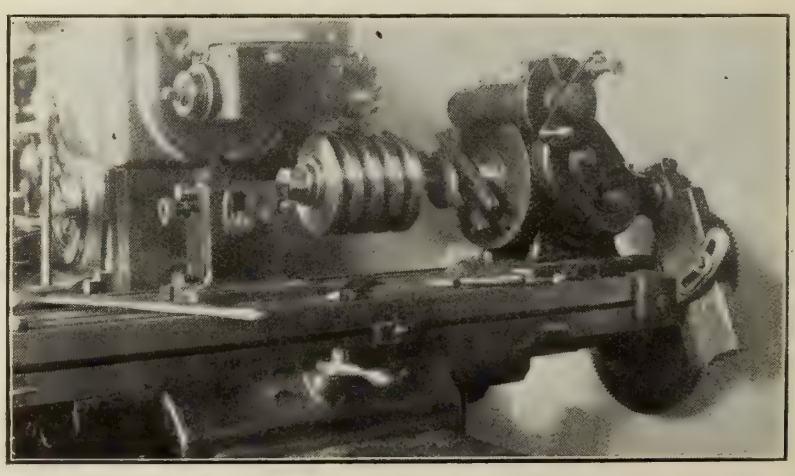
By CHESTER B. HAMILTON, Jr., B.A.Sc., M.E.

THE THIRD group of gears, classified as to shaft arrangement, is those with axes in different planes, but not paralle . A layout of these gears is made upon a plane which contains one axis and is either parallel or perpendicular to the other, so that its projection on the plane of the first may be considered.

This group includes worms and worm gears, helical gears commonly called spiral, and the hyperboloid gear called the skew bevel, from its superficial resemblance to a true conical bevel gear. There is still some confusion of terminology even among engineers intimately connected with the gear business, but the American Gear Manufacturers' Association is trying to straighten out the difficulties that lie in the way of uniformity, in connection with its extensive scheme of standardization.

The sub-classification in the present group is based principally on the form of the pitch surface of the gear in question. The difference is seen in the axial cross section. The common worm has a cylindrical pitch surface, while the Hindley, a special form of worm, has a concaved or hour-glass form which embraces the worm wheel which it mates around a considerable arc of a circle. This arc of course must subtend at the centre of the wheel a lesser angle than twice the pressure angle of the teeth, or it would not be possible to place the worm and gear in mesh. This is on account of the inherent peculiarity of the Hindley worm, that its teeth always point directly towards the centre of the wheel, those at the ends of the worm converging. There is therefore no rolling motion between worm and wheel, and the teeth of each completely fill the space of the other, and bear over practically the whole surface. Thus the area is so great over which the pressure is distributed that a perfect oil film is practically always assured, and with such perfect lubrication the efficiency and durability are high, in spite of the hundred per cent. sliding action of the teeth.

In considering this whole class of gear the words "teeth" and "threads" will be used almost interchangeably, for in the last analysis the worm is a gear of few teeth, and the helical gear a worm with many threads.



Reverting to the sub-classification by form of pitch surface, it is seen that the worm wheels all have concave pitch surfaces, which embrace an arc of the ordinary worm pitch surface at the centre. The Hindley worm wheel embraces an arc of constant chordal length from end to end of the worm. Worm wheels blanks are frequently turned with a cylindrical periphery, and it is likely that the new standard worm wheel form to be brought out by the American Gear Manufacturers' Strandardization Committee will be a somewhat modified cylinder so far as outside is concerned, but the pitch surface is none the less concave. This is essential in order to obtain contact along a line on the tooth surface. A helical gear of the same normal pitch as the worm will mesh with it and act like a worm wheel so far as transmission of motion is concerned, but it is not a worm wheel, and the difference lies in the fact that there is no line contact between the teeth but only contact. The result is very evident when it is attempted to use such gears for considerable loads or speeds, on account of their low efficiency and lack of durability. They are really a helical pair.

Worms are commonly made either by a turning tool in a lathe, by milling with a rotary cutter of disc form, or by end milling with a cutter shaped like a truncated cone. The first and last produce a thread form that corresponds with the tool used, but the disc cutter will not reproduce its own form on account of the drag of the side against the helically curving flank of the thread. This peculiarity is well known in milling machine practice. This may be corrected by using a cutter of altered form which will produce the shape of tooth desired. This interference decreases as the pressure angle increases, and does not occur in milling worms with large pressure angles. Modern high efficiency worms are hardened and ground all over, and are multiple thread, high helix angle and high pressure angle, in both cases well over thirty degrees, and some have been very successful at forty-five degrees.

Worm wheels always have the teeth cut by the generating process. Usually a hob is used, which resembles the worm in form of thread and helix angle, but exceeds it in diameter by twice the clearance at the bottom of the teeth. In addition to being fluted to give cutting edges, the hob when being finish-turned has its surface relieved between cutting edge in spiral fashion so that the face of the teeth, in the flute, may be ground in sharpening without change of tooth form. This sharpening does change the diameter slightly and also the helix angle, which depends on the diameter. In fine work this can be taken care of by setting the axis of a new hob or an old one at a slightly different angle from the average standard.

In hobbing worm wheels the hob is usually fed into the work radially till it reaches the desired depth, but a method of more recent development which has several advantages, is to fix the centre distance of axes with the hob off to one side, and feed it along its own arbor tangentially to the work. A correction in the table ratio gearing is necessary on machines using this process, which is accomplished by impressing the added tangential motion onto the table motion through a differential gear to the table gear drive. The hob in this process is made with its outside diameter conical at the entering end so as to distribute the starting of the cut over a number of teeth. The pitch line and root remain cylindrical.

A machine geared up in this way can, by taking time, generate a perfect worm wheel without any hob at all, by using in its place a slotted cut-

Milling a large worm.

Author is President of the Hamilton Gear and Machine Co., and a member of the American Society Mechonical Engineers; Engineering Institute of Canada; Society of Automotive Engineers; American Gear Manufacturers' Association, Steel Treating Research Society; Standardization Committee of A.G.M.A.; Associate Member of American Institute of Electrical Engineers.

ter arbor and a fly tooth which represents one tooth of an imaginary hob. The rate of production with this fly tooth is of course quite low, but the quality approaches the ideal, for there is no warping of the hob in hardening. The tooth can be ground all over to perfect form. There are no flats—the bane of all hob generating processes—because of the longitudinal feed, which can be made as slow as the refinements of the job require. The longitudinally fed hob, if ground all over would have the same advantages except as to losing form and size as its teeth are ground back with age for tangential feed machines are not generally adjustable for changing helix angle.

Hindley worm wheels cannot be hobbed by the tangential feed system on account of the shape of the hob, which follows the worm form. The same reason indicates one of the principal advantages of the Hindley system.

The worm must be located very accurately in longitudinal position, and special care taken with its thrust bearings to maintain it so, or the perfection of tooth action will be quickly lost. This does not apply to all the cylindrical worm, which requires to be located accurately in two directions only and, fortunately, not in the direction of thrust and wear.

The efficiency of worm gears and all helical gears depends very largely on the helix angle. It increases very rapidly as the helix angle increases, then more slowly as the angle approaches forty-five degrees and again falls off, at first slowly, then more rapidly as the angle approaches ninety degrees. The curve being flattened at the middle, any angle between thirty and sixty degrees can be considered to give first class results. Such a worm and gear are of course reversible in action and for work that requires an irreversible combination, as hoists and the like, a helix angle must be chosen below the angle or fricton, of say twelve degrees.

Helical gears, sometimes called spiral, always have cylindrical pitch surfaces, and, when considered in pairs, always have point contact between the tooth surfaces. Aside from these two definite characteristics, the helical gear may be just about anything, for it occupies middle ground between a number of other more special classes. If a helical gear has few teeth it is a worm, the limit of the definition of the word being about 45 degrees helix angle. If the lead is equal to the pitch, it is a single thread worm, if twice the pitch then a double thread worm. If the lead is zero, that is, the helix angle is zero, then the subject is a cylindrical rack, as is used in some gear shifting apparatus. This is sometimes called a circular rack, but as that term is also loosely applied to crown bevel gears, it leads to confusion. Or another example would be the thrust shaft of a steamship. If the helix angle of the helical gear is 90 degrees, then the gear becomes a spur gear, which is a special case of the helical at one limit of its range.

The angle of the axis may also vary through wide limits. If the shafts are parallel the pair may be spurs or helicals according to their tooth helix angle, this special case coming under a separate section above. For any other shaft angle there is a wide range of possible helix angle of the teeth of each gear of the pair. The limit in one direction is marked by a single thread construction, and in the other by the angle of sliding friction. An impossible case arises when the shafts differ from parallel by twice or less than twice the angle of sliding friction, and the gears are required to rotate in the same sense. They cannot because the teeth will not slide at this low angle. It is a similar case to the irreversible or self-locking worm gear, only that in this case the pair are self-locking in both directions.

Another limit which applies to all cases and must be held constantly in mind in calculating or laying out helical gears is that there must be a whole number of teeth of some standard pitch for which cutters are available. With fixed centre distances and fixed pitches as in the rotary cutter method of forming the teeth, this often leads to impossible cases. The solution is to use the hobbing generating method, select the next smaller whole numbers of teeth, turn the blanks over size by an amount sufficient to make up the difference between the desired centre distance and that given by tooth numbers selected, dividing this increment between the two gears in proportion to their pitch diameters, then generate the teeth by hobbing to the correct working depth. The same method of compensating for fractional tooth numbers can be applied in spur gears or herringbones with the added advantage of being able to use the Fellows gear shaper as an alternative to hobbing.

The most direct way of getting an understanding of the action of a pair of helicals is by laying out a development of their pitch surfaces as they would be unrolled on a plane. Even when the solution of a problem is purely trigonometrical, as it usually is, a skeleton lay-out is an advisable safeguard against confusion of plus and minus complimentary angles, and right and left hand rotation. It is well for any one not continually laying out gears to stick to the fundamentals of geometry and trigonometry, and avoid short cuts.

The disadvantages of helical gears due to point contact, and the resultant lack of capacity and durability have been referred to above. This is serious and prevents this very flexible form of gearing being of nearly the use it would be if it could carry loads efficiently. It is therefore principally used to transmit motion, with relatively light loads, at various odd ratios and in awkward locations, for which work it is well adapted if kept well lubricated. There is a second serious disadvantage of this form of gear, and that is the end thrust that is always present when the helix angle is appreciable, and becomes serious when it is above the angle of sliding friction. Thrust washers, etc., are used for low angles, but roller or ball bearing must be used for low angles, but roller or ball bearings must be used for satisfactory results and constant operation at the higher angles.

The skew bevel gear or hyperboloid is not a true bevel, for the pitch surface is not a cone but a hyperboloid of revolution. This is the surface that is swept out in space by the revolution of a line about another line to which it is not parallel and which it does no intersect. This figure is somewhat of an hour-glass form with narrow throat and flaring ends. Supposing we have two of these hyperboloids, the surface of each of which is made up of straight line elements, it will be possible, in any except some special cases, to lay them against or across one another with their surfaces tangent throughout the full length of a line, which will be one of the generating elements common to the two. The pair of skew bevels then would correspond to two conjugate transverse sections or frustra of the hyperboloids. Their common tangent would correspond to the pitch line contact of a pair of teeth just as in bevel gears. If the transverse sections were selected at the narrow middle portion or throat of the hyperboloid, the two gears would superficially resemble a helical pair, but would differ in having concave pitch surfaces and line contact. The angle of axis of the two gears depends upon the angle between the describing elements and its axis and their distance apart, or throat radius. Of these two quantities for the two gears, three must be known or assumed to determine th fourth geometrically. The right angle pair is a special case. For convenience in manufacture the throat radius of gear and pinion are usually made equal, that is, the line of action of the tool is a contant distance above (or below) the work arbor axis on the machine.

There is another special chase sometimes used to simplify the work, which is to make the throat radius of the pinion zero, which reduces it to a common bevel. The pinion cone centre then lies on the throat circle of the hyperboloid which contains the gear. This class of gear is so difficult to calculate and make that it is practically never used where it can be avoided. Shaft positions might sometimes compel its adoption, but it would be better to re-design the whole machine and avoid freak constructions.

(To be continued)

Mill scale and adverse weather conditions promote corrosion of steel. Mill scale and all rust must be removed before any paint is designed to protect the clean steel surface. The second coat of paint protects the first coat from the weather and this second coat must, therefore, be impervious to moisture and frost.

Soldering Fluxes for Machine Construction

Formation of Oxide Should be Avoided—Methods of Preparing the Various Fluxes—Preventing Corrosion—Uniting Dissimilar Metals by Soldering

By W. S. STANDIFORD

THE MAINTENANCE forces in all shops and factories have to face many difficulties when machines break down, as it is the rule to restore them to normal working conditions as soon as possible and "in a jiffy," as delays in production costs money the result being that a machinist or millwright has to work at his highest speed with a chance of mistakes in measurements made and good metal and time wasted. Soldering coppers (called soldering irons or bits) are used to a more or less extent in repairs and machine construction work, the craftsmen having to deal with such metals as wrought iron, cast-iron, steel, copper and aluminum, each one requiring a different kind of flux so that firm joints can be made.

Removal of Oxide

The necessity for using fluxes in soldering exists in the fact that an oxide that always forms upon all brightened surfaces of metals, has to be removed by this flux, the latter by thus preventing formation of oxides, allows the solder to stick directly to a metal's body, instead of an oxide film which, sooner or later, allows the joints to come apart. Having stated the reasons for use of fluxes; their formulas will now be gone into. As most all of the copper soldered joints consists of electric wires on dynamos, motors and commutator risers, etc.; extreme care will have to be taken in order to avoid corrosion at the junction caused by the electric current going through the wire. A most excellent flux for all electric as well as for other copper work, is made by carefully melting 2 ounces of rosin and 2 ounces of vaseline. The mixture should be well stirred and poured into an empty baking powder can. This flux should (when cold) be of the consistency of butter, so that a small particle will stay on a joint. As rosin varies in density a little more of it may have to be added.

A liquid flux for copper electric wires is composed of 5 parts of a saturated solution of zinc chloride, 4 parts alcohol and glycerine 2 parts. The saturated solution of zinc chloride is made by filling a bottle half full of hydrochloric acid, then adding small strips of sheet zinc, a few at a time, until the acid will dissolve no more. Mix alcohol and glycerine together and add to the acid mixture. The operation of dissolving zinc strips in the acid should be done in the open air on account of the suffocating fumes generated which are injurious to the health.

Iron and Steel Flux

A fine flux for uniting wrought iron and steel articles is made by dissolving sheet zinc in muriatic acid until it will dissolve no more; then diluting this mixture with twice its amount of water and next adding a small lump of sal-ammoniac. The latter assists the solder in adhering, and is excellent in protecting the soldering iron from corrosion. The chemical action of the above flux depends upon the fact, that muriatic acid unites with iron or steel and in doing so, it deposits a film of zinc on the article to which the solder will most readily adhere. In using any acid flux all joints should be well washed and dried to prevent corrosion. An excellent flux for steel parts which will not blacken or rust the work, is made of alcohol 6 ounces, 2 ounces glycerine and 1 ounce of oxide of zinc. Cast iron a difficult metal to solder so as to make the parts hold together, but this can be easily remedied by brightening both surfaces and coating them with a film of copper. Copper solution is made by putting a few crystals of copper sulphate in a small bottle of water; shaking until dissolved. Put on with a brush and the joints will turn copper colored. Copper sulphate is a poison and should be handled with care.

Soldering Aluminum

Aluminum is a difficult metal to solder but if the work is done with a solder and flux of formula given, it may be soldered with the least amount of trouble.

Aluminum Solder Formula

84 per cent tin.
16 per cent aluminum.
3 per cent copper.

Melt copper first, add aluminum a little at a time, stirring constantly with an iron rod. Then add the tin and also a small piece of tallow the size of a penny. Stand a dry grooved board upright, stopping groove ends with wooden plugs and pour the hot metal into groove thus making the solder into sticks as thick as a lead pencil. Use a soldering iron made of aluminum. The flux is composed of equal parts of tallow and rosin, after melting, add half the quantity of zinc chloride to this mixture. Two other aluminum solders that will prove useful for uniting sheet aluminum or rods are as follows:

Number 1 Formula

80 per cent tin.
20 per cent zinc.
1 per cent aluminum.

As a flux, use a bar of common yellow laundry soap. Heat the metal parts to be united with a blow torch to about 650 deg. Fahr. Then quickly rub the hot surface with bar of soap and tin well with the solder, pushing the latter backwards and forwards which removes the oxide. When both sheets are "tinned" with solder, heat and apply pressure on joint until it is cold. An aluminum soldering bit will be found to work better than a copper one, although the latter can be used successfully for aluminum work. Both can be "tinned" with either of the solders listed, using their fluxes.

Number 2 Formula

72 per cent tin.
23 per cent zinc.
3 per cent aluminum.
2 per cent phosphor tin.

As a flux, use either stearic acid or yellow soap. Both solders will give a strength to a joint nearly equal to the metal itself. The only thing to avoid in soldered aluminum joints is corrosion, where it is exposed to dampness.

Preventing Corrosion

Corrosion can be prevented by varnishing the joint with several coats of spar varnish. In ordinary locations these solders will be found to resist corrosion, on account of the large amount of tin contained in them. In constructing new and repairing old machines, it is often found desirable to combine steel or iron parts with brass ones, and thus obviate the necessity of using screws, bolts or rivets for fastening them together. The main drawback heretofore, has been due to the unequal expansion of the combined metals; brass expanding double in amount to that of iron or steel and preventing all adhesion between their surfaces. The following alloy, however, sticks firmly to iron and steel pieces and will be found to give satisfaction. Melt 39½ parts copper, then add 3 parts of tin and also 7½ parts of zinc. Stir well and cast into sticks or narrow strips as preferred.

Uniting Dissimilar Metals

To use, heat the iron or steel pieces sufficiently hot to melt borax, brighten surface with a file and put enough borax on it to preserve its brightness. Treat the brass surface to be united, the same way, using borax. Put your strip of alloy metal between the brass and steel parts, tieing with wire if necessary to keep them in place; then heat until the alloy melts; hammer the sections together and let cool slowly. When cold any machining operations may be proceeded with. This combination flux and borax can also be used to unite pieces of high-carbon tool steel to a shank of cheaper soft machine steel, for lathe or planer

News From the Welding Field

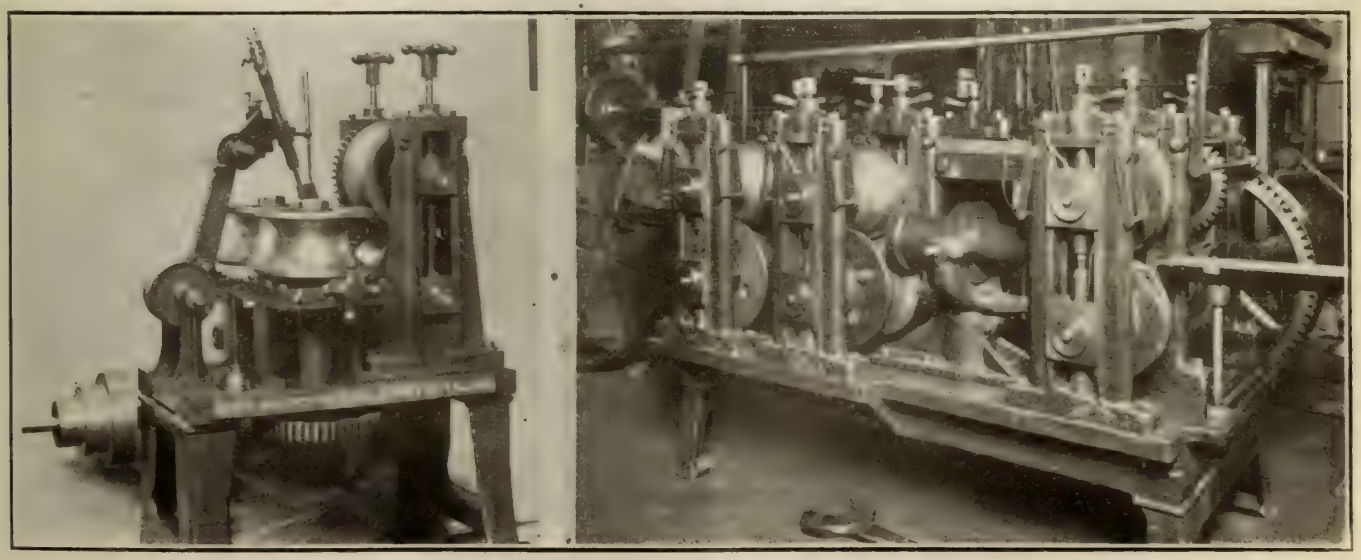
Automatic Seam Welding in Making of Tubes

Material Must be of Suitable Composition—Finger Arrangement Prevents All Twist or Curl When Strip Stock is Entering Rolls—Compressing the Metal After Weld is Made

By J. L. ANDERSON

THE success of an automatic operation of whatever nature, requires the utmost care in the construction of the mechanism, the preparation of the work, and the uniformity of the motion required. Automatic welding is no exception, and in fact requires even more care because the welding operation is autogenous (self produced) and is the result of a combination of temperature, exterior pneumatic force, speed and mechanical pressure; a variation in degree of any one of these may be fatal to the success of the operation.

In order to be assured of final success, it is essential that material must be provided which is of suitable composition, reasonably accurate in thickness, and within much closer limits as to width in addition to having absolutely square edges. Some manufacturers use only strip stock in coils, others use in addition considerable sheet stock, while a few use sheets entirely. The advantage in using sheet stock being the ability to produce tubes of any usual diameter promptly, by slitting the sheets in a gang slitter. There is, however, more waste in meeting the requirements as to the length of tubes.



Paper read before the Schenectady, N.Y., section of the American Welding Society, February 8, by the author, who is welding engineer of the Air Reduction Co.

When preparing to manufacture welded tubing of any size or nature, consideration must be given to the purpose for which the tube will be used, the finish required and the temper or hardness desired or permissible, and from this point work backward to arrive at the proper width of strip and the gauge necessary to meet these requirements, the characteristics of the steel being known. In explanation, we will assume that a tube is required which must be accurate as to internal and external diameter; to meet this requirement it must be cold drawn with triblet inside. When drawing is required, it is customary to produce a tube approximately 1/32 in. over finished size, and in order to make a tube hold its shape when rolled it is necessary to have a strip of metal which is from 1/32 to 1/16 in. wider than actually necessary to form a circle of the required size, this excess metal is apparently lost in the compression of the tube while being formed, resulting usually in a slight increase in length of tube over that of the flat strip. From these remarks it will be readily understood that it is essential to be prepared with a full compliment of spacers for the slitting machine and rolls for the tube forming mills, with variations in size to meet any requirements as to the finished tube.

The gang slitter is of the usual type with the exception that the cutter shafts are of heavy alloy steel, with keys fitted the entire working length, with gearing arranged so that simultaneous adjustment of the bearings is provided, thereby maintaining accurate alignment and making possible the adjustment of the over-lap of the cutters to suit various thicknesses of metal. On these shafts are placed forged cutters ground to extreme accuracy and of such form that resharpening is done by grinding the face, thereby maintaining the original accuracy throughout the life of the cutter. Between the cutters are placed spacers alternating with a wide and narrow spacer on each shaft in order to bring the cutters in such a position that the cutting section action is identical on each edge of the metal, thereby preventing curling of the strip. When the spacers and cutters are all assembled on the shaft in sufficient number to cut the entire sheet, they are then locked by the adjusting nuts at the extreme end of the shaft.

Elimination of Curl

A unique feature in connection with the slitting of sheets is the finger arrangement, which prevents the strips while being cut from wedging between the cutters and are adjustable so that all tendency to twist or curl is eliminated. In order to make possible the changing of cutters and spacers, the end housing is arranged to withdraw and swing on

Left—Tube welding machine for large diameter, thin wall tubing.
Right—Tube forming mill, with three sets of rolls and conical conductor.

a table provided for this purpose. For supporting the strips and sheets there is provided at each end a table which is usually of a length approximately that of the longest sheets which are to be cut. On the feeding table, guides are provided which position the sheet in relation to the cutters so that there is always a trimming taken off each edge in order to produce equal conditions on all strips. The machine most commonly used cuts an entire 36 in. wide sheet into strips at one pass, the speed being about 50 lineal feet of sheet per minute.

Tube Forming Mill

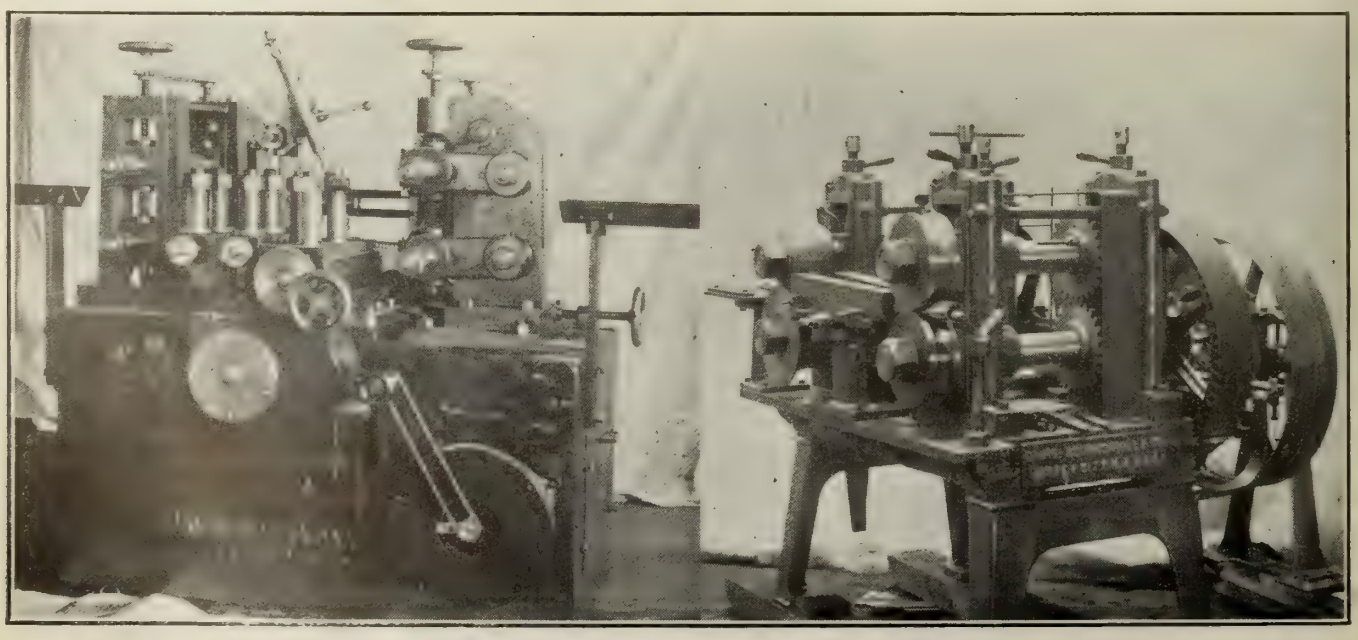
The most popular type of forming mill for the production of open seam tubing is of the two-stand type, comprising one set of break-down rolls, conductors for guiding the tube from the break-down rolls to the finishing rolls. In order to properly position a strip, there is provided an adjustable guide in advance of the break-down rolls which when set up in perfect alignment with the center line of the rods, guides the strip through the break-down rolls so that both edges are brought to the same degree of curvature, after which the strip enters the conductor, being propelled through the conductor by the break-down rolls, and while passing through the conductor being changed gradually in form from a section of a large diameter circle to that of an imperfectly formed "U" of the size approaching that of the finished tube; the real object of the break-down rolls being to produce a form of strip which will have sufficient rigidity to withstand the resistance to the deforming operation without buckling, and at the same time be presented to the finishing rolls in proper position for compressing to a perfect circle with edges in close abutment.

If you can visualize the gradual formation taken by a flat strip approximately 30 in. long in changing from a flat section to a circle you will realize what takes place in the formation of a tube in the tube forming mill. The natural tendency in the formation of a tube from a flat strip is to curve downward, the seam being on top due to the stretching of the edges, which is unavoidable, and must be counteracted while the strip is passing through the machine. This is accomplished by the adjustment of the conductor in relation to the center of the finishing rolls, the operation being that of depressing the nozzle of the conductor below the center line of the rolls in order to produce a compressing action on the edges of the strip. This action occurs previous to the final formation of the tube in the finishing rolls, and therefore corrects stretching and allows the tube to leave the machine perfectly straight.

Preventing Wind

There is another difficulty which must be corrected, and that is the unequal stretching of the edges causing the seam of a tube to wind. This tendency is corrected by two methods, one is the adjustment of the guide previous to the strip entering the break-down rolls, the other is the adjustment of the conductor, latterly, or sometimes a combination of both adjustments.

When it is desired to use strip stock in coils, a support for the coil is provided and a swinging cut-off saw is mounted on the delivery end of the machine. This is used in conjunction with an automatic stop which makes possible the production of formed tubes cut to length. The automatic stop is actuated by the tube when it has reached a certain length; this stop throws out the clutch and at the same time causes a braking action, stopping the mill instantly. At this time the operator moves the motor driven swing saw by hand, thereby severing the tubes. The variation in length will seldom exceed 1/2 in. by this method. The maximum hourly production of a machine forming and cutting tubes to length will seldom exceed 2,000 feet, whereas with the use of strips previously cut to length the machine runs continuously without stopping, and will usually average 3,000 feet per hour.



It is of the utmost importance that the roll and tube equipment of the forming mill be extremely accurate, and the machine adjusted to produce accurately-formed straight tubing without twist, in order to make possible automatic operation of the tube welding machines.

The tube welding machine is in reality a mechanism for propelling an open seam tube at relatively slow speed by means of accurately machined rolls driven through reduction gearing. This reduction minimizes the slight fluctuations in speed of the driving mechanism due to various causes, and makes possible the maintenance of a puddle of molten metal of considerable area, extending entirely through the thickness of the metal at the desired point.

Counteracting Strains

There is another function of the machine not usually apparent, which is the compression of the fused metal after solidifying. It is this compression, or working of the heated metal, which assists in the production of the exceptionally strong ductile welds produced by mechanical welding. Still another feature of the machine is the mechanical means of counteracting the contraction strains set up by the welding and compressing operation, combined with the rounding and sizing of the tube as it leaves the machine. This is accomplished by an adjustment of the rolls in relation to each other so as to cause a bending action on the tube, while hot.

In order to be assured of perfect tubing, the roll equipment must be very accurate and it is by no means uncommon to produce tubes on the welding machine within a variation of .005 from size and mainly on the cheaper grades of tubing,

Left:—Tube welding machine with overhung rolls.
Right.—Tube forming machine, with two-piece adjustable conductor between rolls.

roundness. Strange as it may sound, accuracy of this degree is practised and for the purpose of eliminating subsequent finishing and sizing operations.

The tube welding machines are usually made right and left hand, in order to allow the grouping of the machines so that when possible one operator can take care of two machines. The accepted method of driving machines of this type is by means of adjustable speed direct current motors, with field rheostat and push-button station mounted on the machine, the magnetic control panel used for operation in connection with this equipment may be placed at a distance, if desired. This equipment provides for forward and reverse motions, together with dynamic breaking, which relieves the operator of the necessity of throwing switches—a simple touch of the correct button automatically taking care of the operation of the machine. The rolls are individually adjustable for alignment, while the welding or compression rolls are in addition adjustable vertically.

On account of usual high speed of the driver, a reduction is made through worm gearing running in oil, and from this point through beveled gearing to the spur gearing, driving the roll equipment. For light gauge tubing, the rolls are placed between housings, the machine being of light construction yet ample for welding tubing much heavier than usually encountered. For changing the rolls equipment from one size to another, it is customary to remove one housing, which is arranged with slots for this purpose.

Wide Range of Machine

A very important feature is embodied in these machines, in order to make possible the welding of all diameters and gauges under the best possible conditions, that is, the adjustability of the guide roll and housings in relation to the welding rolls; the rapid absorption of heat in light gauge large diameter and small diameter tubes causing more or less distortion in passing from one set of rolls to the other, unless this distance is adjusted to counteract this tendency. The speed of welding the ordinary diameters and gauges of steel tubing is usually performed between 3 and 6 feet per minute; the speed varies as the thickness of metal varies, and to some extent in order to secure particular types of welds. It is the attention to small details, such as mentioned in the manufacture of machines of this type which makes possible real automatic welding.

For welding large diameters and heavier gauges, a tube welding machine is provided which is of a very much heavier construction, arranged with all rolls over-hung, making possible the changing of rolls from one size to another by simply removing the holding nuts. The same features of adjustability are incorporated in the larger machine; all bearings subjected to heat, however are watercooled, it being essential to use torches and tips of much larger capacity in welding at higher speed, or heavier walled tubing. While the large machine is primarily intended for welding large diameter heavy gauge tubes, medium diameter light gauge tubes can also be welded at a very much higher speed than possible on the machine previously described.

In addition to the roll equipment usually found on tube welding machine, there are added two additional pairs of compression rolls whose function is to prevent the rupture of the seam and recompress the metal, which, at higher speed, requires a longer interval of time to drop below the critical temperature due to the greater absorption of heat.

A feature common to both machines, and which is particularly necessary when welding at the higher speeds, is a universal torch adjusting arm which makes possible instantaneous movement of the torch in any direction, as well as movements controlled by thumb screws vertically and radially, together with provision for throwing the torch to a horizontal position for lighting and inspection.

Adequate Supply of Gas

Having a machine which embodies all the essential features and the required accuracy in construction, it is even more important to have an adequate supply of gases at absolutely unvarying pressures, also apparatus for burning the gases with flames so positioned as to take advantage of the physical changes in the tube while undergoing the welding and compressing operation. All other conditions being constant, the position of the flames in relation to the seam, and particularly the welding rolls, has a decided influence on the character of weld produced.

It is important that an interval sufficient for the solidification of the metal be allowed before the compression occurs, in order to prevent cracking while passing through the machine, therefore the final flame of the torch must be in advance of the center line of the two compression rolls. Any advance beyond a certain point requires more compression and tends to produce heavy welds which are usually undesirable on account of the cost of removing the excess metal.

Almost all tube and mechanical welding operations to-day employ the multiple flame welding tip. These tips may have any number of flames within the capacity (of the machine and work) to absorb the heat produced, to say nothing of the endurance of the person who must operate the machine.

Wave Formation

A person who has witnessed a welding machine in operation having a single flame tip in use, undoubtedly noticed the wave formation of the molten metal, seemingly traveling ahead of and around the flame, finally solidifying in the rear of the flame, and if the motion was unsteady, leaving wave marks indicating a long tapered wedge shaped puddle. The wave formation with a multi-flame tip is more pronounced due to the fact that every flame (which is the result of the combustion of gases under pressure), causes a series of waves, the depth of the hollow and the height of the wave above the actual surface of the metal increasing as the heat is absorbed, and the metal acted upon by each succeeding flame.

The remarks regarding the agitation of the metal due to the velocity of the gases, discloses the reason for the accuracy required in tool equipmen used in the production and welding of the tubing, together with the necessity for absolutely uniform speed and constant gas pressures. Welded steel tubing made from suitable material with the proper amount of care exercised in its manufacture as outlined, will go through the usual crushings, flanging, expanding, bending, and other tests usually performed on seamless and lap welded tubing in order to indicate its qualities.

Grinding the Weld

Welded tubing is usually finished by grinding to remove all evidence of the weld and produce a tube of uniform contour, this grinding operation being performed preferably on a motor-driven grinding machine, arranged for two operators working simultaneously, and with foot treadles controlling the pressure placed upon the tube necessary to quickly remove the surplus metal. The usual practice is to have the machine equipped with flexible buffs, coated with abrasive, and with the periphery curved so that when a tube is placed in the machine at an angle of approximately 30 deg., the wheel covers a considerable portion of the space and thereby prevents the grinding of flat and irregular spots on the surface of the tube; the operation being that of moving the tube backward and forward so that the operator can continually see the condition of the tube he is working on. When the tubing is welded with the idea of producing a strong weld with the least possible amount of finishing required, it is not uncommon for an operator to grind 4,000 or 5,000 feet of tubing per day. After grinding, the tube is ready for the finishing operation, which may be either swaging or drawing.

Swaging Operation

The swaging machine is of the rotary type which embodies a hardened steel ring pressed into the head of the machine inside of which there are a number of rolls, usually ten or twelve, these rolls being mounted in a steel cage which is free to rotate, while inside of the rolls there is the arbor of the machine which, at this end, is slotted in order to accommodate the dies and the hammers which are machined to the proper form so that when thrown out by centrifugal force are brought into contact with the rolls, and due to their form pass from one roll to the other with a smooth rolling action, thereby producing on the dies which are between these hammers a squeezing action, rather than a hammer blow, each contact with the rolls producing a slight rotation of the cage carrying the rolls.

Practical Ideas for Shop Executives

SELECTION OF MATERIAL FOR GAUGES

By Henry James

The selection of material for gauges, depends largely on the gauge to be made, and its use. For flat gauges, such as profile or templates a good grade of low carbon or machine steel can be used with very good results, as it can be more readily worked and is not so easily affected by temperature changes. Plug and ring gauges require a higher grade of tool steel, and care should be taken to select steel that is free from pipes. This is, perhaps, one of the most difficult points to discover, as the piping in a bar of steel cannot be seen until the work has reached the hardening process. Steel for thread gauges should be selected with great care. A fine, close grained steel, which, when hardened and tempered, will show least distortion, should be selected. A test piece should be taken from the bar and machined and carefully measured, then hardened and tempered and again carefully measured to determine the effect heating has had upon it.

SUGGESTIONS FOR WOODWORKING DEPARTMENT

By Donald A. Hampson

The woodworking department that forms an adjunct to many machine shops often furnishes some difficult problems for the upkeep gang. This branch may have from one to a dozen machines in it—an equipment to do the patternmaking, packing, boxes and special containers, and general woodwork about the plant. Loose pulley repairs and rebabbitting are always a part of the maintenance work. Then there are mandrels to be straightened, machine heads to balance, etc. In recent years, safety requirements have necessitated extensive alterations and these alterations, after some years of trial, have proven themselves good from the production standpoint as well. One of the most noticeable is the round head for planers and jointers.

Shops that do not have these round heads are urged to change for their own good. They are much simpler to make than the old fashioned square heads—they may be turned out of a round bar and after turning there is no milling to do but for the two cutter slots. The improved static and running balance (and its continuance,) is one of the good features. A good many shops have saved the expense of new knives by milling down the old ones: the square head knives were, say, 7-16 in. by 3½ in. when new, of composite steel; these have most of the soft back cut off and make ideal safety head knives 3-16 in. by 1½ in. leaving all the good tool steel portion intact. These round, or safety, heads do smoother work than the square ones because of the better balance, if for no other reason. And they please the factory inspectors immensely. Then, because the blades set out from the head so little, there is less splitting of the wood as it is run through.

The old argument comes up—whether to put in two, three or four knives. Every shop has had workmen who advocated more than two knives—every shop has had salesmen come along and try to get it to buy new planer or jointer heads with three or more knives in them. But the very best advice that can be offered is, "Never Use More Than Two Knives." It is possible to make any number of knives cut alike but it is not commercially possible and any shop that fusses with them is wasting money. The time spent by the average man in trying to set three or four knives alike is time wasted—why, examine any head that has but two knives in it and the chances are that one knife will show plainly that it has been doing most of the work!

The only practical way to make more than two knives cut is to grind them, with one of the portable attachments, right in place on the head; and even then the conditions of running unbalance are more than likely to throw the work on one, two, or three of the knives. One of the most skilful wood working men in the section scorns to use more than two knives: "Why waste my time on something that don't show for it?" is his motto. And when it comes to a special job on the shaper or variety machine, he makes up only one knife, or blade, and puts a dummy in the head opposite, to balance up.

A case came up not long ago that will bear repeating. We had a big planer and it required frequent re-babbitting and dressing of the shaft. Everything seemed to balance all right on the ways and the repair gang certainly did good work on their part. Finally, it was conjectured that the driving pulley might be the cause of the trouble; accordingly, this 35 lb. pulley was removed and a wood pulley substituted. The planer has now run four times as long as previously between pourings and is still going well. This proof seems to show that the cast iron pulley was pounding out the bearing, vibration being set up under the belt stresses and speed.

PUTTING A BAND ON A BAR

By F. Scriber

A fixture having but four major parts that performs a rather important function is shown by the accompanying drawings. The purpose of this fixture is to bend the steel clip over a brass rod of rectangular shape, this rod is recessed as will be noticed from the assembly drawing Fig. 1. The clip is made in U shape by a punch and die. This clip A with both ends sticking up is placed by hand in the recess of the bar B, it is then held by one hand while the operator moves lever C first to the right and then to the left. This lever which is attached by a stud D to a formed piece E having two curved extensions thereon pushes down first one side of the clip and then the other side of the clip, the lever being down in its extreme left position with the clip forced down. The body of the fixture F is held to the punch by screws through holes G, it simply being made to support the work and the operative members.

Fig. 2 shows a detail of this block F which is made of cold rolled steel having an extension thereon at the 1¼ inch dimension over which the part shown below in the same illustration operates.

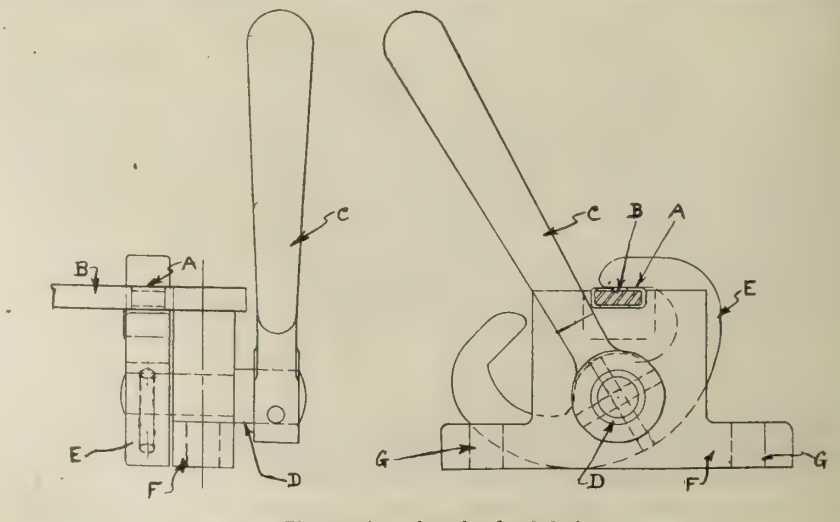

Fig. 1.—Assembly sketch of device.

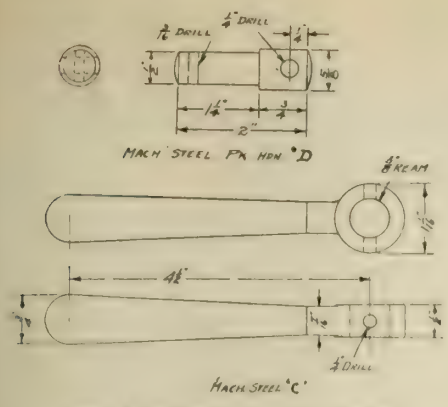

Fig. 3.—Details of lever and stud.

In Fig. 3 are shown details of the lever and stud which are pinned together by means of the quarter inch holes which have a pin driven through them, a pin is likewise driven through the piece E (having the curved extensions) to hold it to the stud D. The simple nature of this fixture for performing such an important function is one that has a very strong appeal.

HOW TO FIGURE BELTING

By W. F. Schaphorst M. E.

The question is often asked: "How can I figure fabric and Balata belts? I see all kinds of rules for leather belts but I seldom see anything about fabric belts."

In reply I have the following to offer. I have avoided the use of formulas and tables entirely in order to simplify the method as much as possible. Formulas and tables are often very vexing.

Balata Belts:—Let us suppose that you want to figure that width of a Balata belt necessary to transmit a given horse power. Proceed this way: Subtract one from the number of plies, multiply by the diameter of the pulley in inches, multiply by the number of revolutions the pulley makes per minute, then multiply by 0.000158 and then divide the result into the horse power to be transmitted. The answer is the width of the belt in inches. If you get 1.8 inches for the answer you will very likely decide on a two-inch belt in order to be safe, which is the right thing to do. If you get 2.01 for an answer you will decide that a two inch belt will do the work very capably and you will be right because these rules allow for an ample factor of safety. This rule is usable for Balata belts of 3, 4, 5, 6, 7, 8, 9, or 10 ply.

Fabric Belts.—Now for fabric belts. The rules as ordinarily given for fabric belts made up in plies are something like this—"A 4-ply stitched canvas belt is equivalent to a single leather belt. 8-ply is equivalent to a double leather belt." And so forth. Then after knowing the equivalent we have to hunt up our rules of thumb for leather belts before being able to decide on a width necessary for a given drive. Here is a rule which gives the direct answer without even thinking of leather. The rule applies to most ordinary belts made up in plies such as rubber and stitched canvas. Divide 2,640 by number of plies and to the quotient add 136; then divide the result into the speed of the belt in feet per minute; and then multiply that result by the width of the belt in inches. The answer is the number of horse power that the belt will transmit. For example, what horse power may be transmitted by a 10-ply canvas belt whose width is 6 inches and whose speed is 4,000 feet per minute? Substitute in the rule just given above and you will find the answer to be 60 horse power.

To find the width of a stitched canvas or rubber belt, proceed this way: Divide 2,640 by the number of plies and add 136 to the result, then multiply by the horse power to be transmitted and then divide by the speed of the belt in feet per minute. The answer is the width in inches. To find the speed at which a stitched canvas belt may be run, knowing the horsepower and width, proceed in this way: Divide 2,640 by the number of plies as before and add 136; then multiply by the horse power to be transmitted; and then divide by the width of the belt in inches. The answer is the speed in feet per minute. To find the number of plies to specify, knowing all other factors, proceed in this way: Multiply the width of the belt in inches by the speed of the belt in feet per minute and divide by the horse power to be transmitted; then subtract from that the number 136; then divide the result into 2,640. The answer is the number of plies.

Speed:—To find the speed of a belt, knowing the diameter of the pulley and the revolutions per minute—Multiply the diameter of the pulley in inches by 0.262 and the result by the number of revolutions per minute of the pulley. The answer is the speed of the belt in feet per minute. To find the number of revolutions per minute that will be made by a given pulley, knowing the speed of belt and diameter of pulley, proceed in this way: Multiply the diameter of the pulley in inches by 0.262 and divide the result into the speed of the belt in feet per minute. The answer is the number of revolutions per minute. To find the diameter of pulley, knowing the speed of belt and the revolutions per minute, proceed in this way: Multiply the number of revolutions per minute of the pulley by 0.262 and divide the result into the speed of the belt in feet per minute. The answer is the diameter of the pulley in inches.

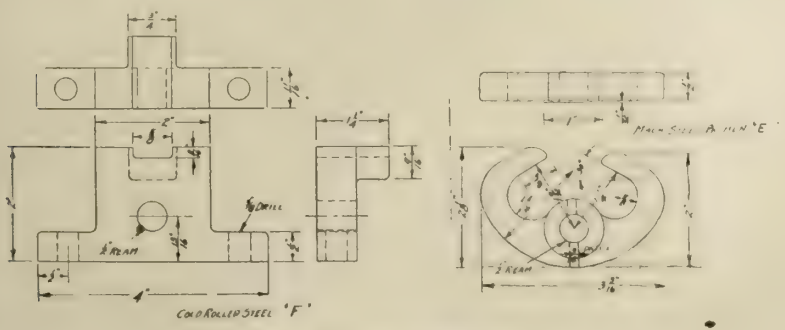

Fig. 2.—Details of block F.

CLEANING OILY MACHINE PARTS

One of the most troublesome of the minor problems in the repair and overhauling of motor cars and other machinery is the perfect cleaning of parts which have been thoroughly soaked in oil. This problem is very ingeniously handled in the new central repair works in connection with London's great motor omnibus service. The parts to be cleaned are placed on wire trays mounted on a conveyor which moves very slowly through a cylindrical casing inside which are mounted on a number of pipes perforated with holes ⅛ of an inch in diameter. Hot caustic solution is forced through the pipes by a pump, and the multitude of jets reach every part of the gear wheels and other portions of machinery passing through. When the parts emerge from the cylinder they are practically free from oil. In this way a process which generally is most prolonged and laborious is perfectly carried out in a minute or two.

AUTOMATIC CONTROL FOR HYDRAULIC PRESSES

The hydraulic press is a very ancient as well a very widely used machine, and it finds one of its most profitable applications in the seed-crushing industry. In order to secure the highest economy in seed crushing, the first part of the operation should be done at low pressure and the final stages at high pressure. Hitherto various mechanical arrangements have been employed to effect the control of pressure, but a British firm has just introduced a special valve by which the pressure is automatically controlled without the use of any mechanical details. From beginning to end the device operates without supervision and does its work much more accurately than with the old type where the change in pressure was carried out at the discretion of workmen. The arrangement is extremely simple, and tests made on it go to show that its use will increase the oil yield from linseed by one half to one per cent. while making a 50 per cent. reduction in the fluid which can be squeezed out of the cake.

The plant of the Snider Flour Milling Co., at St. Jacobs, Ont., was destroyed by fire recently, with an approximate loss of $100,000.

CORRECT UNDERSTANDING OF MECHANICAL VIEWS

(Continued from page 43)

object within are drawn. It is necessary to construct our understanding of planes and axes with a concrete example, even though it is imaginative. This gives us a base to proceed from and establish the different planes and axes from which views are supposed to have revolved.

The object that we wish to draw is assumed to be placed within this transparent box and the views drawn upon the surfaces facing the different views. (These have been shown shaded to stand out clearly.) The top or plan view is made on top of box, and we say it is drawn on the horizontal plane. This plane is revolved 90 degrees on the horizontal axis until it lies on the same plane as the front view which is drawn on the front vertical plane. This front vertical plane is assumed to be stationary.

The end view is drawn on the side vertical plane and that plane is revolved so that it is on the same plane as the front vertical plane. This plane revolves on the vertical axis.

The drawing depicted in Figure 2 shows the three planes as they would be represented on a drawing, the points on the side view are traced around from the top view by swinging arcs from the intersection of the horizontal and vertical axes and projecting down to the end view.

A thorough understanding of the different relations existing between the views should assist in eliminating unnecessary mistakes and loss of time in interpreting the draftsman's meaning; that is if he knows himself how to put his proper views on the paper.

Editor's Note:—The author seem to be taking a sly dig at draftsmen in general when he says at the conclusion of his article "that is if he knows himself how to put his proper views on the paper." From personal contact with draftsmen in Canada we find that it is only in exceptional cases the maker of the drawing projects his views other than third angle. Usually English or Scotch draftsmen are inclined to use first angle style until they become used to the new conditions in this country.

SOLDERING FLUXES FOR MACHINE CONSTRUCTION

(Continued from page 46)

use. It is fine for machine parts where heavy friction is encountered. For fastening hard and soft steel parts, it is much better to use strips of sheet copper and borax between them; heating both metals in a blacksmith's fire until the copper is melted and hammering both pieces of steel to effect a junction. They should then be plunged into a hardening bath of salt water. Do not quench the entire surface of tool, but leave some heat in the shank to allow drawing to a proper color of the hard steel cutting edges.

The above method of working saves time by not requiring reheating of the hard tip to draw to the desired tempering color, that quenching of shank and tip in the hardening bath would make necessary. When the desired color is reached, this salt water hardening bath is most excellent to dip the tool into to prevent any further extension of the colors, as it removes all oxide scale and imparts a silvery whiteness to a cutting edge. In the repairing of various kinds of machinery, the use of welded sections containing a steel having a carbon content of somewhat lower amount than tool steel, such as 0.88 per cent. will prove of value in places on machinery exposed to heavy wear as it allows of hardening and tempering the rubbing parts to such an extent, that it will make them continue in action for a longer time than would be the case if their wearing surfaces are made of a softer metal and casehardened.

The 0.88 per cent, carbon metal has the great advantage in repair work, that it can be welded to a wrought iron part of any machine very quickly and easily in a blacksmith's fire, only borax being needed. This results in much time being saved in getting machines into action after a breakdown occurs. Steel can be used for machine parts, but where there is heavy vibration, it is better to use wrought iron with a hard steel welded piece on its wearing surface, as wrought iron does not crystallize by vibration.

CHARGING HOIST FOR FOUNDRY CUPOLAS

The P. H. & F. M. Roots Co., Connersville, Indiana, have designed a charging hoist to reduce fatiguing manual labor, with its accompanying cost. In addition, they have developed this machine to save much in maintenance of refractory linings of cupolas. Many losses are directly traceable to faulty methods of charging, which result in expensive delays very often overlooked. The hoist is operated by electrical power, either from overhead or floor, and is designed to pick up pig iron or scrap on an electric magnet and deposit same in an iron melting cupola by means of a cantilever charging arm, attached to the hoist frame. Magnet is interchangeable by means of an automatic hook with a drop bottom bucket for the charging of fuel and flux in cupola.

By charging with a hoist with cantilever arm, all materials to be charged are deposited in cupola concentric with the center line of cupola, which evenly distributes each charge. The materials being charged on the center line do not come in contact with the refractory brick lining in cupola, consequently materials do not cut away this lining. This is impossible where charges of materials are fed by hand, dumped from cars or charged by chutes through charging doors of cupola. If such means are employed, materials bank on one side of cupola and as such a charge works down melting becomes uneven, because the air blast seeks the line of least resistance until the materials on the low side of bank are all melted, thus giving a direct outlet for the air blast, which in turn will help cut the refractory lining in cupola. In addition to this the materials which are banked on the high side become slightly chilled because insufficient air is supplied for proper combustion. This condition often necessitates, at the end of a long heat, the dropping of the bottom with a large amount of material not melted.

By mechanical charging with a magnet on the center line of cupola, the great volume or weight of iron charged at one time will help pack the bed down and keep forcing materials into the melting zone without arching or bridging over. Under the present charging system, the tendency of arching or bridging in the melting zone is always present, and this arch or bridge holds until a sufficient amount of materials has been added to force it down. During this period of arching very little iron is melted, which sometimes causes long delays in securing molten metal and many times requires a shutdown until this arch or bridge is broken.

An extremely simple, quick change, automatic hook on magnet and bucket enables the operator to lower hoist ropes with "U" bolt into funnel-shaped hook, which by gravity slides down incline to center line of hook, and when hoist ropes are reversed upward "U" bolt automatically engages with hook. This hook also forms a guard for ropes and magnet cable when hoisted and telescoped into charging arm, preventing damage from heat and swinging while depositing charges in cupola. To release hook operator has only to lower and travel hoist back until ropes are on an angle; then the hoist ropes and "U" bolt disengage the hook and slide up the incline and out of the hook casting.

WELDING BY CLOCKWORK

In shipbuilding and in many engineering operations, it is necessary to fix brass studs and other small parts to iron plates. This operation is usually performed by drilling holes in the plate, each hole being drilled separately. By means of an ingenious invention recently perfected by a British firm, the process is carried out in a few seconds by electric welding. The working of the machine is almost entirely automatic from the moment the stud is placed in position. Each size of stud requires a different time for welding it to the plate, and the machine can be set to give exactly the period required to make a perfect weld. The tests which have been made proved that the machine is able to weld 120 brass studs within an hour. It might be thought that welding does not give such a firm arrangement as screwing the stud into a hole in the plate, but when the welded stud is hammered the brass will break before the weld yields. Another advantage of the machine is that work can be satisfactorily carried out by semi-skilled labor.—*100-ton Booster.*

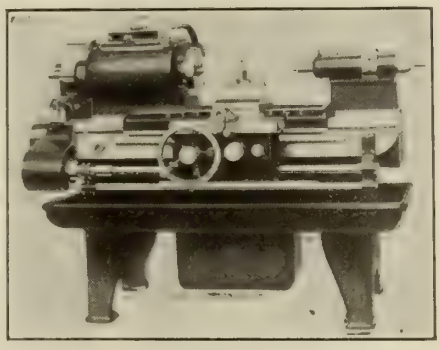
New Things in Shop Equipment

AMPLIFYING GAUGE

Two smaller sizes of a well known amplifying gauge have recently been placed on the market. The smaller gauges are limited in range and do not have all the attachments of the larger gauge. It is made in two sizes, one of which is intended for work from ¼ in. to 2in. in diameter, and the other for work from 2 to 4in. in diameter. The firm manufacturing these gauges is the American Gauge Co. of Dayton, Ohio.

MOTOR DRIVEN DISC SANDER

A very useful electric disc sander has recently been placed on the market. It is particularly adapted for accurately sanding segments, angular sections, coreprints, and circular and taper work. It can also be used in machine shops for medium and light metal work. The steel disc plate is fifteen in. in diameter, and is easily removable for renewing the sandpaper or emery cloth on its face. The speed of the disc is 1725 r. p. m. The table has a groove to receive angle and circle segments, and duplicating gauges. The table tilts 45 deg. downward from the horizontal plane and 25 deg. upward. A graduated index is provided to show the angle at which the table is tilted. A vertical table adjustment of six inches provides for handling a variety of work. The angle gauge is graduated from 0 to 45 deg. both to the right and left to permit of accurate settings. Alternating or direct current motors are provided. The motor is coupled to the disc shaft in such a manner that it does not receive thrusts from the latter. A push button control switch is located on the column. The machine is portable and electricity can be taken from any light socket. The manufacturers are the Oliver Machinery Co. of Grand Rapids, Mich.



REAMER DRIVING MACHINE

To facilitate the reaming of finished holes to size in the assembly of machines or mechanical units, a device for driving hand reamers has been placed on the market. It is capable of driving hand and machine reamers up to 1½in. in diameter. The mechanism is mounted on a pedestal and power is supplied by a motor mounted on bracket about half way up the pedestal. The motor is a 1/6 h. p. machine that can be used on either direct or alternating current. The power is transmitted to the horizontal spindle in the mechanism by means of a round belt. A three-step cone pulley provides three specific spindle speeds, of ten, twenty, and thirty r. p. m. respectively. The operator stands directly in front of the machine and feeds the work on the slowly revolving reamer. The reamer centres itself. The spindle is fitted with a 5in. Cushman geared scroll chuck. The end thrust of the machine is taken up by ball bearings. The gears in the gear case run in oil. The control switch is of the self-contained tumbler type. It is claimed that work is reamed much more quickly than if it were done by hand and that the finish is much better. The distance from the floor to the centre of the spindle is 38 inches. The machine is portable and weighs about 145 pounds. It is manufactured by the George H. Blettner Co. of Chicago, Ill.

12 IN. MANUFACTURING LATHE

The lathe here shown has recently been placed on the market. It is designed primarily for manufacturing purposes, but if it is desired for thread cutting this can be arranged by substituting a lead screw in place of the feed rod.

The general design of the lathe is the same as the 9 in. machine. The headstock is of selective speed, the drive single pulley type with a very powerful friction clutch to the large driving pulley. The same movement that disengages the clutch automatically applies a brake which stops the spindle instantly. For attaching air cylinder, draw-in

12 in. Sundstrand lathe.

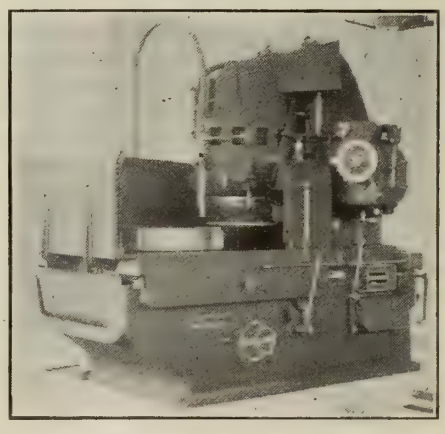
attachment, expansion chucking device, etc., an extension is provided at the outer end of the spindle. Main spindle taper bearings are made from high grade bronze bearing metal, adjustable for wear by means of a single nut at the rear end of spindle, providing an instantaneous adjustment. A special feature on the carriage is the multiple stop collar which makes a positive stop for the cross slide when turning shafts with shoulders and different diameters. The carriage which has exceptionally long bearing surfaces on the ways and is arranged with slide block for taper attachment, has lugs on top, drilled and tapped to permit the mounting of extra cross slides, special tool holder blocks, etc. The apron is of improved double wall type, very simple with a minimum number of working parts and gears. A feed reverse box, of bevel gear and clutch type, very simple in construction with steel gears and bronze shaft bearings, is regularly furnished. A quick acting tailstock is supplied as standard equipment. Taper attachment, draw-in attachment and rear tool block can be furnished. The machine is manufactured by the Rockford Tool Co. of Rockford, Ill.

EXPANDING CYLINDER REAMER

One of the recent tools that have been placed on the market is a reamer or boring head intended for refinishing automobile cylinders and having an expansion of approximately ⅜ of an inch. The head may be screwed on to the end of a boring bar and then used on machines of different types. The adjustable members of the head are concealed and protected within the head itself. Thus dirt and all foreign matter is excluded, and cannot interfere with the making of adjustments. During an adjustment the blades remain in the same relation to one another, therefore do not require regrinding to true them up. To adjust the tool eight screws on the face of the head must be loosened. These screws hold the front plate firmly and when held tightly in place, the plate acts as a lock for the individual cutters. As the screws are loosened the plate is pressed outward by four coil springs in the body. When the plate has been pressed out sufficiently the blades are then free to move in the radial slots in which they are contained. A centre adjusting screw on the face forces the blades outward or inward as desired. After an adjustment has been made the eight screws are tightened and the plate locks the blades in place again. The reamer is made in different sizes up to 4½in. in diameter. It has been widely used in turret lathes and other machines used in quantity production. The reamer is manufactured by the Campbell Auto Works of Stockton, Cal.

POWER PRESS PULL OR PUSH FEED

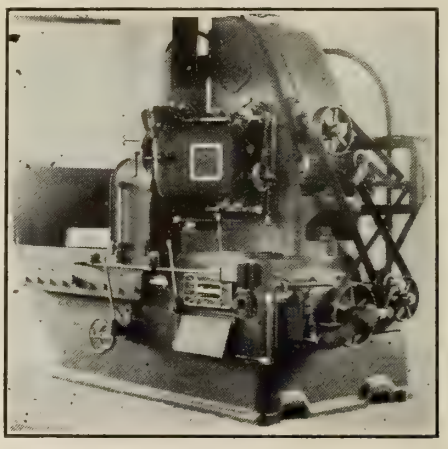
There has been placed on the market recently an attachment for power presses that provides for the automatic feeding of stock of various widths. The fixture can be applied to any make of power press. The casting on which the members of the mechanism are mounted, is attached to the bolster plate of the press by means of four cap screws which pass through slots in the casting. This method of attaching permits of the shifting of the cap screws to suit the holes in the bolster plate. Power for the



mechanism was obtained by placing an eccentric crank on the main shaft. By means of a gripper, the stock is moved forward. When the stock has advanced to the required position over the die a trip on the gripper comes into contact with an adjustable dog and releases the hold of the gripper on the stock. A rod then pulls the gripper back and while this movement is taking place an adjustable retaining pawl prevents the stock from moving. When the gripper has returned to the desired point the trip engages a second adjustable dog which re-engages the stock for the next operation. A handle on the gripper provides for releasing its hold on the stock at intermediate points when necessary. The operation of the device is positive, and by adjusting the position of the dogs the stock may be fed to the die without unnecessary waste of material. The apparatus can be arranged to either push the stock to the die or to pull it, as is desired. The manufacturers are the Walsh Press and Die Co., of Chicago, Ill.

CHAMFER GRINDING FIXTURE

A fixture has recently appeared on the market which is intended to be used in grinding thread chasers in such a way as have all chamfers exactly alike. When the chamfer on a set of chasers is not the same on all the individual chasers, the burden of cutting comes on one or two chasers with the result that threads are cut out of lead, tapered, or with other irregularities. The fixture is principally designed to grind chamfers on the milled form of chasers made by the manufacturers of the fixture, but it may also be used for grinding chasers of the tapped form. With chasers of the latter form the grinding is straight and does not conform to the contour of the chaser threads. The table of the fixture is graduated and may be set for grinding long or short chamfers. A narrow key engages the keyway of the chaser and acts as a guide while grinding. An adjustable stop governs the position of the chaser with respect to the grinding wheel. The side of the fixture is also graduated to enable the table to be tilted accurately to the desired angle of the chamfer clearance. One table accommodates all sizes of chasers both right and left hand. The fixture is bolted to the table of a grinding machine and the chaser is slid forward by hand to the wheel, and against the stop provided on the fixture. However, on those machines that permit of so doing, the chaser may be fed forward by means of a machine hand-wheel or lever to a stop arranged on the machine. The fixture may also be mounted on a machine slide and the chaser ground by passing it back and forth across the edge of the grinding wheel. The manufacturers are the Geometric Tool Co. of Bridgeport, Conn.



HEAVY DUTY VERTICAL GRINDING MACHINE

There has recently been placed on the market an exceptionally large machine for surface grinding. The general dimensions are 12 ft. 6 in. long, 7 ft. 6 in. wide, and 10 ft. high, with a weight of 30,000 lbs.

Blanchard High-Power Grinding Machine.

The work is carried on a rotary magnetic chuck, 48 inches diameter which is moved horizontally from the loading to the grinding position, and there rotated continuously while the wheel is gradually fed downward. Owing to its size and weight the chuck and table is traversed by power. In other respects the operation is like smaller sizes of the same make although the mechanism is different. The grinding wheel is 27 in. diameter, 7 in. deep, with rim either 2 in. or 3 in. thick. It is sulphur mounted in a cast iron retaining ring, attached to the faceplate by six screws, and is wire-banded. The wheel head weighs 3 tons and has built into it a 60 horsepower, 600 r. p. m. induction motor. The rotor is directly on the wheel spindle, which is 5½ in. diameter and is carried on two large radio-thrust ball bearings. A spring take up at the upper end exerts an upward pull on the spindle which exceeds the weight of the rotating parts by 1,000 pounds. This initial load on the lower or main thrust bearing eliminates all play or backlash. The main bearing has a rated thrust load capacity of over 25,000 pounds.

Rear view of Blanchard grinding machine.

The wheel safety guard is of 5/16 in. steel plate, carried on three heavy steel rods, and has a convenient rack and pinion mechanism for vertical adjustment. A wheel dresser attached to the head provides for dressing or sharpening the face of the wheel while grinding. There is the usual water supply to inside of wheel through a 2 in.-pipe and to the outside nozzle through a 1½ in. pipe. The head is mounted to slide vertically on a massive column. The usual three point support is used to fasten the column to the base, thus making it easy to secure and maintain proper alignment.

The vertical motion of the wheel head is controlled by a heavy feed screw, 4½ in. dia., carried in a ball bearing in the column. This screw is driven through a gear box mounted in the column, receiving its power from the upper pulley. Double friction clutches provide for rapid raising or lowering of the wheel head. Both hand and power feeds are provided by means of the box on the front side of the column. The power feed has an automatic stop, also a convenient adjustment, giving feeds from .0005 to .005 inches per revolution of the chuck. A single lever controls the engagement of the power feed, and the raising and lowering clutches, and is arranged so they cannot be simultaneously engaged.

The chuck is driven through a four speed sliding-gear box, with friction clutch for starting and stopping, interlocked with the gear shift. Power for all purposes, except driving the wheel, is supplied by a 5 horsepower motor. The rotary magnetic chuck for holding the work is 48 in. dia. and is of the Blanchard one piece steel type. It has closely spaced poles suitable for holding either small or large work. The face is of brass and steel and is absolutely waterproof. The chuck is carried on a substantial table, sliding on the base on one flat and one V way. This table spans the base like a bridge and all water and metal from the work fall directly into the first part of the water tank in the base, where most of the solid material settles to the bottom. From here the water overflows into the rear part, under the column, where any remaining material can settle. The water then flows under a skimmer, which holds back floating dirt, and over another dam into the pump tank. The first part of the main tank is cleaned from the left end, and the second part has a large clean-out opening near the right hand end on the front. Both parts are so arranged that the entire bottom can be reached with the hoe provided, and an inclined end leading to an overhanging drip edge makes it easy to remove the mud into any receptacle. The pump tank is accessible for cleaning but rarely requires it. The total water capacity is 425 gallons. The machine is made by the Blanchard Machine Co. of Cambridge, Mass.

Important Machine Development

THE ADVANCEMENT made in machine tool design during the last decade has been phenomenal. Every industry could at least show one case where machinery has taken the place of hand labor, with resultant saving in time, energy and money. Take for example the travelling crane, the mechanical piler, the gravity conveyor, the air hoist, and hundreds of other mechanical devices which have almost eliminated hand labor in some industries.

Trucks and other forms of commercial vehicles would never have reached the present state of development had it not been for machine tool and gasoline engine designers, and the same holds true in other lines of manufacture. Even in road building and track laying, the machine supersedes to a large extent the laborer. The modern method of laying a street car intersection, is to start late in the evening with a gang of men, supplemented with modern machinery, and have the cars running over the new intersection the following morning. Instead of using the old time pick axe, we now have the steam driven pavement breaker, and air tools for varied purposes. The air compressor is usually self contained, and in addition we have the electric welder busily engaged making rail connections. To get his power, he merely connects a pole to the trolley wire overhead.

The latest to feel the benefit of modern machinery is the cotton industry. Human labor has played an important part in this trade for over 4,000 years, but now hand picking of cotton will soon be a thing of the past on the modern plantation, as an electrically operated picker has recently been perfected and placed in operation. With the new machine, it is possible for one person to gather from 400 to 700 pounds of cotton per day, as compared with 70 to 150 by hand. This solves the greatest problem of the cotton grower for it allows him to harvest all his crop before the rains and frost damage the plants. It will allow the cotton to be picked when ripe, thus improving the grade and adding about $10 to the value of every bale.

One of these days, someone is going to start a movement to erect in the capital city of each country, a monument to machine tool designers, for without their help and advice, the world would never have reached its present stage of development. More and more, the art of machine tool design is becoming specialized, engineers devoting their entire time to some particular branch of industry. The result is that these men become experts in that particular branch, and produce machines of the highest efficiency.

Interest in Workmen's Compensation

THE QUESTION of workmen's compensation has aroused great interest among manufacturers, so that the article on this subject, appearing on another page, is both timely and interesting. Our contributor desires to remain in the background, but he holds an important executive position, and has made a close study of the subject for several years. His object in presenting the article is two-fold. He wishes to give readers information, but also desires to start discussion, therefore every manufacturer should write us his opinions on the subject.

No one will question for a moment the benefits derived from the act during the past seven years. It has helped the employee, saved employers undesirable litigation, and has resulted in every employee getting full benefit from any payments made. The expense of running the board is low, being only two per cent. of assessment made, so there can be no criticism on that score.

No matter how well an organization is run, there is always room for improvement, and the points brought out in the article deserve careful consideration. If employees are forced to contribute to the fund, by means of premiums, they will, no doubt, try to get as much out of the fund as they put into it. This will undoubtedly increase malingering, and those in authority should weigh the matter carefully before proceeding with the premium suggestion. There is also the question of additional clerical expense involved in collecting these premiums. Considering every angle of the situation it is very doubtful if the hoped for benefits would justify the means.

We have already emphasized on this editorial page the importance of selecting only the best type of doctor available for treatment of injured employees. As we mentioned in our April 20 issue, inefficient doctors are a menance to industry and should be eliminated as soon as possible.

So far as statistical information is concerned, there is a great need for some quicker method of supplying manufacturers with figures showing individual records. Once start the practice and a competitive spirit will be automatically aroused which will tend to materially reduce not only compensation costs, but the number of accidents.

With such reports coming in, every manager would be anxious to show the best record in his own particular group, and would do all in his power to make his plant safe. A quicker return of figures would entail additional clerical expense, but would pay in the end. Those responsible for the compiling of accident records should do all in their power to speed up the service. Monthly reports are necessary and would fill the bill admirably. We cannot expect the improvement to be sensational in character, but the sooner the present methods are improved the better. When a manufacturer receives 1920 figures in 1922 it shows conclusively that the present system is poor and of little worth in checking the cause of the trouble.

* * * *

DO YOU believe in the use of "Goggles?" If you don't, read the article on page 36 of this issue which shows how the goggle problem was licked in one plant. If you do believe in their use, read the article anyhow, for it makes mighty interesting reading.

Everything the author has said is absolutely true, and if other plants were to adopt a similar policy, less eye accidents would occur. There are some industries where the element of danger is greater than in others, but in practically every industry, the danger of flying chips or particles is existent, resulting in many cases in the loss of an eye.

Prices Remain Firm In Iron and Steel Lines

April Demand Slackened Off Slightly in Some Lines—Better Business Expected This Month—Building is Active—Coal Strike Has Not Restricted Steel Production up to Present Time

GALVANIZED SHEETS ARE LOWER IN PRICE

CANADIAN markets show a slightly better tone. Although nothing outstanding has occurred during the week, a spirt of confidence exists, in spite of the fact that April business in some lines was not as good as March. This is easily understood when we figure that there were only 21 actual working days in April, owing to holidays and Sundays.

Iron and steel continue in fairly good demand, prices being firm in bars, small shapes, etc. The price of 28 gauge galvanized sheets is under fire, some claiming $5.55 to be the market figure. Anyone knowing the market closely can purchase at $5.35, and the same is true of Premier No. 28 sheets. No advance s been made in steel prices of any kind, competition being too keen to allow merchants to take a chance.

The non-ferrous market shows a slight improvement, consumers displaying added interest. Prices, however, remain the same.

The demand for pig iron has tapered off, but during the past few weeks, many consumers have been able to get under cover. In fact, although the present price of pig iron is now up $2 a ton since April 20, the mills are chiefly working on orders at the old figure. This shows how well consumers protected themselves.

Machine tools are doing a little better, new tools making a better showing than for some time past. No large orders have been closed, but the total volume of business is not disappointing. Second hand tools are still moving, but not as briskly.

Scrap metals are firm, but as the demand is not very great, the firm price means very little. Oils and waste are moving at a fair rate, the latter showing a ten per cent. increase in April over March.

Small tools and supplies are quieter, at least so the majority find it, although one large merchant reports a 35 per cent. increase in orders during April, over the previous month. This, however, is the exception, rather than the rule. The automotive industry is very busy, this helping the small tool field.

Building activities are proceeding nicely, and Montreal especially reports that materials of this nature are in good demand. Steel pipe shows added strength, deliveries longer than ever, owing to the demand. In fact, some business in certain sizes is being turned down.

The steel market in the United States has now assumed the aspect of a sellers' market. The mills decide what orders they will accept, and price cutting is practically non-existent, even on very desirable orders. Instead of hindering, the coal strike has really been a good thing for the steel industry.

The production of steel ingots at present is between 36,000,000 and 38,000,000 tons a year. This is about a million tons more than the March average. Distributors and manufacturing consumers are less active on the finished steel market, but a fair amount of orders are still coming in. The complete steel market can be said to be moderately active, but not quite as lively as at the end of March.

Production at the mills is about 70 per cent., and in all products, the regular market prices are being rigidly adhered to. Bars, shapes and plates are selling at 1.50c, bands, hoops and hot rolled strips at 2.00c, and blue annealed sheets at 2.40c.

The pig iron market has practically disappeared. Several furnaces have had to bank owing to coke shortage. A recent sale of basic was made at $24, and the market may be quoted as $24 valley, against $19.50 for Bessemer, $18 for basic and $19 for foundry on April 1. There is little enquiry for foundry coke as foundries have already stocked up quite freely.

Toronto

May 3rd.

THERE is no question but what general conditions are improving on the local market. A few dealers complain about the rate of recovery, but the majority of merchants are content to see the slow but gradual improvement, feeling that after all, a slow steady recovery is better than a sensational rise, only to experience a further set back at a later date.

Iron and Steel.—This market was somewhat of a disappointment in April, because compared with March it just breaks even. In fact, some claim that April business was less than March, but when one considers that there were only 21 actual working days in the month, the reason is self apparent. Last week, the demand, while general, was not very large, this helping to show a poor total for the month.

Dealers and merchants generally expect good business this month, and the consensus of opinion seems to be that small shapes and blue annealed sheets will be the active members. May is usually a good month, and present indications point that way. Prices remain unchanged, and until Canadian mills advance their quotations, dealers will not take a chance, competition being too keen. Existing prices are firm in bars, and the quotations noted below are being strictly adhered to.

Quite a bit of argument is going on regarding galvanized sheets 28 gauge. Some claim $5.55 is the nominal price. Don't believe it, for the man who knows his market can secure all he wants at $5.35. The same holds good regarding Premier No. 28 U. S. sheets. Should dealers use the argument that $5.35 is given only in good sized orders, lose interest, and see how quick they will meet the lower figure. At present no particular line is featured, and the coming week is being watched carefully by all merchants.

Other dealers look for increased activity in boiler tubes this month, as several plants are contemplating boiler repairs. Following are existing quotations:

Iron bars	2 75
Steel bars	2 75
Reinforcing bars	2 75
Steel hoops	3 75
Tire steel	3 00
Spring steel	6 00
Band steel, No. 10 gauge and 3-16 in. base	3 25
Small shapes	3 00

Pig Iron.—The $2 increase which came into effect April 20, is now a settled fact. The demand is slightly better than a month ago, but has tapered off from the volume of two weeks ago, when every consumer was rushing for cover. In fact, so many managed to get in at the old price, that the mills are still producing at the low figure.

Foundries have a fair stock on hand, and unless the coal strike assumes a more dangerous aspect, it is unlikely that any further rush for material will take place. The local price is $29.15 and recent buyers find that no concession is allowed on this figure.

Non-Ferrous Metals.—Red brass and copper shows a little added strength this week, but nothing of great importance. Prices remain the same, but consumers show more interest. Following are present quotations:

Lake Copper	17 00
Electric Copper	17 00
Castings, copper	16 50
Tin	34 00
Spelter	7 25
Lead	6 75
Antimony	0 8
Aluminum	26 00

Scrap Metals.—Prices remain stationary on this market, but improvement in demand is noted. There is a little better tone throughout this section, and red brass shows the best strength of all. White metal is weak, steel scrap is fairly strong but the mills are only in the market for a limited tonnage. Cast iron is firm, but in no line is a heavy volume of business moving. Following are present prices:

Copper, light ..... per 100 lbs.	8 00
Copper, crucible	10 50
Copper, heavy	10 50
Copper wire	10 50
No. 1 composition	8 50
New brass cuttings	6 00
Red brass turnings	6 00
Yellow brass turnings	4 75
Light brass	3 50
Medium brass	4 50
Scrap zinc	3 25
Heavy lead	4 00
Tea lead	3 00
Aluminum	10 00
Boiler plate, per gross ton	9 00
Heavy melting steel	10 00
Axles (wrought iron)	16 00
Rails (scrap)	10 00
Malleable	11 00
No. 1 machine cast iron	16 00
Pipe, wrought	6 00
Car wheel	16 00
Steel axes	15 00
Mach. shop turnings	6 00
Stove plate	14 00
Cast boring	5 00

Machine Tools. — A fair amount of business is being closed on this market and although the rate of selling is far from normal it is encouraging. Buyers are showing a keener interest, and new tools are selling at a better rate. One dealer says that 60 per cent. of his business last month was in new tools, this being quite a change from his March experience, when second hand tools were in chief demand. No orders have been closed, but the total volume of business in April shows a slight improvement over March.

Small Tools and Supplies.—A peculiar condition exists on this market. With one exception, dealers claim that April was a disappointment, the volume of business being less last month than in the previous one. The exception, however, states that his small tool and supply business increased 35 per cent. in April, and proved his statement by showing us figures for the different sections. Pumps showed themselves to be the feature, valves and steam goods, transmission equipment, and general supplies, following in order. In fact, this particular dealer finds business so good that he is sending two more men on the road, although he has eleven travelers busy at present. According to his statement, last week reminded him of the old war days, so great was the demand during that period. This does not apply to the complete market locally, but only to this merchant who is out very aggressively after business.

Steel Pipe.—The demand for steel pipe continues, and in some cases orders are being refused, where sizes are not in stock. Consumers are afraid of the coal strike, and are trying to cover their requirements. Delivery rests with the mills, and they are doing the dictating. Prices remain the same, but should there be any change it would be upward.

Waste and Oils.—The demand for waste and oils shows a slight increase. April business in waste denotes a 10 per cent. increase over March, but oils are about the same in April, as in the previous month. Following are existing quotations:

OILS AND COMPOUNDS

Castor oil, per lb.	34½
Royalite, per gal., bulk	21
Palacine	24
Machine oil, per gal.	33 00
Black oil, per gal.	17 50
Cylinder oil, Capital	61 50
Petroleum fuel oil bbls., net	9 90
Pure turp., single bbls. gal.	1 35
Linseed oil, raw, single bbls.	1 00
Castor oil, per lb.	34½
Royalite, per gal., bulk	21
Palacine	24
Machine oil, per gal.	33 00
Black oil, per gal	17 50
Cylinder oil, Capital	61 50
Petroleum fuel oil bbls., net	9 90
Pure turp., single bls. gal.	1 35
Linseed oil, raw, single bls.	1 00

Montreal

May 3, 1922.

BUSINESS has not changed during the week. Activity in building operations continues, this being largely made up of residential buildings, apartments, and stores with living quarters above. A few office buildings are under construction, also a limited number of industrial extensions. Building materials are in better demand than they have been for several years.

Iron and Steel.—From practically all quarters there comes the statement that the coal strike will have a great influence on the iron and steel markets, although up to the present no advance in quotations has been made.

If an increase does come it may not be directly caused by the strike. The small volume of business passing has not drawn on the supplies of jobbers, or of the mills to any extent. Conditions in the States are continually becoming brighter and it is only a matter of time before the better tone will be felt locally. It has been suggested that as British quotations on steel and iron products are not much higher than the American quotations, if the strike lasts, perhaps some steel might be imported. This is hardly likely to be carried out, as before the steel could be delivered, the strike might be settled.

Structural shapes continue to move fairly well, and merchant bars are also in nominal demand. Plates are very quiet. Galvanized and blue annealed sheets are in fair demand, but are not moving as well as they were a short time ago. Spikes, nails, and small steel products are in somewhat better demand, and local quotations remain the same in all lines. These are as follows;—

Iron bars	2 75
Steel bars	2 75
Reinforcing bars	2 75
Steel hoops	3 75
Tire steel	3 00
Spring steel	6 00
Band steel, No. 10 gauge and 3-16 in. base	3 25
Small shapes	3 00

Pig Iron:—No. 1 pig iron is still quoted at $31.80 locally, with a tendency to stiffen. Up to the present, producers were quoting until the end of June, but it is stated on good authority that in the near future pig will not be quoted beyond thirty days. This decision is being made because it is thought practically certain that higher quotations will prevail in the coming months. Locally, many of the small foundries have come into the market recently for car lots, and this together with some larger orders have swelled the tonnage up to a point where business may be said to be fairly active.

Machine and Tool Supplies:—No increased activity can be reported in the machine tool field. Sales for last week have been rather limited, and consisted mostly of small tools. Woodworking tools are removing somewhat better, but business is still spotty in this line. No price changes have been made, and as far as can be ascertained, none are contemplated. The supply market has been somewhat better during the week as jobbing shops are getting more business, and in some instances are pretty busy.

Non-Ferrous Metals.—In spite of the fact that in the United States and British markets the volume of business passing in non-ferrous metals has been steadily improving for the past two weeks, there has been very little change in the small volume of business passing locally. Prices have stiffened somewhat in sympathy with foreign quotations, but aside from this no change has occurred. Lead and spelter are both very firm, and the local quotations are as follows.—

Lake Copper	16 75
Electric Copper	16 50
Castings, Copper	16 25
Tin	35 00
Lead	6 75
Spelter	7 50
Antimony	6 50
Aluminum	23 50

Scrap Metals:—The volume of business in this market is about the same as last week. Prices have stiffened a little due to the demand for this class of material in the States. The market has been extremely quiet for months and the present turn for the better has been very welcome to dealers. Local stocks are not heavy, as very little effort has been made to collect the material. Quotations are as follows:—

Copper, light ..... per 100 lbs.	8 00
Copper, crucible	10 50
Copper, heavy	10 50
Copper wire	10 50
No. 1 composition	8 50
New brass cuttings	6 00
Red brass turnings	6 25
Yellow brass turnings	4 75
Light brass	3 00
Medium brass	4 50
Scrap zinc	3 25
Heavy lead	4 00
Tea lead	3 00
Aluminum	10 00
Boiler plate, per gross ton	7 00
Heavy melting steel	9 00
Axles (wrought iron)	17 00
Rails (scrap)	10 00
Malleable	10 00
No. 1 machine cast iron	18 00
Pipe, wrought	7 00
Car wheel	17 00
Steel axes	16 00
Mach. shop turnings	4 00
Stove plate	16 00
Cast boring	3 00

Pittsburg

May 3rd.

THE COAL strike has not restricted steel production, for the rate is slightly heavier than a month ago, and the market is stronger than ever. It is strictly a sellers' market, in that the mills decide what orders they will accept, instead of cutting prices to get almost any kind of an order. On the whole, the coal strike has proved a very good thing for the steel industry.

Of course there is the superficial showing that at some points steel production would be greater if production of Connellsville coal and coke were not restricted, but then it might be too great, and if there had been no coal strike, or expectation of one, steel demand might not have been as heavy during the past three months, as it has been.

Production in the Connellsville region is about one-third what it was in March, and has been approximately stationary for the past ten days. It is quite unlikely these non-union strikes will extend farther, but it is improbable that the men will drift back to work in large numbers in the very near future. They must do so eventually, for the Connellsville region has always been non-union, and it is absurd to think of its becoming union, under the control of the United Mine Workers, in the very year in which the U. M. W. so prosperous and powerful in the past quarter century, is likely to lose its chief foundation, the check-off. The check-off may be described briefly as automatic unionism, the dues, fines and initiation fee being deducted by the payroll clerk and remitted in a lump sum to the district office of the U. M. W. The union operators are determined never to agree to the check-off again, and the non-union operators are not going to become union at a time like this.

Iron and Steel.—Only a part of the iron and steel industry depends on the Connellsville region, where these non-union strikes occurred. The union strike was fully expected, and ample provision was made for it. The Connellsville strikes, however, were not expected, and there has been striking in some other non-union districts, but not enough to have much influence on the general coal situation. The Connellsville strikes are important.

The iron and steel industry has now had a month to adjust itself to this unexpected condition, and is lined up for a very fair production indefinitely. The Steel Corporation uses Connellsville coke almost exclusively in its Pittsburg district and valley mills, having other sources of supply for Cleveland, Lorain, Chicago, etc. The corporation has bought coal freely on 30, 60 and 90 day contracts, much of this being West Virginia and Kentucky coal for the Clairton by-products coke plant, the largest of its kind in the world. The corporation's production in the affected district is slightly reduced, but production in other districts is increased. Much the same condition obtains as to independents.

Production of steel ingots at the present time may be estimated roughly at between 36,000,000 and 38,000,000 tons a year, against rates of 35,000,000 tons at the end of March, 30,000,000 tons at the end of February and 20,000,000 tons during December. Thus, if there should be a material reduction in output later, on account of the coal strike, which is improbable, the rate would be set back only a few weeks and would remain much heavier than a few months ago.

Many distributors and manufacturing consumers bought finished steel products heavily in February and March, in anticipation of possible trouble in deliveries on account of the coal strike set for April 1. They are now less active in the market, but buying from other motives has arisen. Some of this is attributed to the fact that mills have got back to their normal gait, and are scheduling rollings two or three weeks in advance, whereby one cannot depend upon instant mill shipment on a new specification and must round out stocks. Then there is no doubt some increase in actual consumption, while the railroads week by week are somewhat better buyers. Thus the steel market is moderately active, though probably not as active as at the end of March.

The steel mills are comfortably filled with business for the next two or three months at their present rate of operation, production being about 70 per cent. capacity, and having little margin in which to increase production, on account of the coal strike, they are in a very independent position. A few are showing their attitude by announcing to the newspapers "advances" in their prices. There are some mills that are conspicuously free in cutting prices when the market is weak and asking extra prices when the market is strong. The majority try to peg along with as few changes as possible.

In all products the regular market prices are being quite rigidly observed, concessions to secure particularly desirable orders having disappeared so far as can be seen. The market is quotable as follows: Bars, shapes and plates, 1.50c; bands, hoops and hot rolled strips 2.00c; standard steel pipe, 71 per cent. basing discount; blue annealed sheets, 2.40c; black sheets, 3.15c; galvanized sheets, 4.15c; automobile sheets, 4.50c; tin plate, $4.75. Wire nails show a divergence, as the independents are adhering to their recently advanced price, $2.50, while the Steel Corporation retains the old price of $2.40. Mills are well sold up on nails.

The pig iron market has practically disappeared. Only a few of the merchant furnaces in this general territory were running on April 1, and on account of the stringency in Connellsville coke, on which they depend so largely, some have had to bank. The furnaces have practically withdrawn from the market and there is little inquiry, so that there are hardly even nominal prices. However, a sale of basic iron was made a few days ago at $24, so that is considered the market, and Bessemer and foundry would not sell at less than basic, so that the market may be quoted nominal at $24, valley, against $19.50 for Bessemer, $18 for basic, and $19 for foundry on April 1.

There is little bidding for Connellsville furnace coke as merchant furnaces could not afford to pay the prices which would be asked. A little buying by steel interests has made a market of $6.00, against not over $3.50 at the end of March and $2.75 to $3.00 in January. There is little inquiry for foundry coke, foundries having stocked up freely, but there is some buying here and there, by which a market of $6.50 has been developed, against $4.25 to $4.75 in March.

SCHEME TO DEVELOP BRITISH TRADE

Under the auspices of the British World Trade Expedition, the 9,000 ton steamship known as British Trade will sail in June from the port of London on a cruise around the world with an exhibition of representative British manufactures and industries. It was originally intended that this ship should leave on May 1, but the engineering dispute caused a postponement of the sailing, and the actual date has not yet been definitely fixed

The cruise will occupy 267 days, of which 119 will be exhibition days at the various ports. In a voyage of 38,000 miles the steamer will visit thirty ports, including Rio de Janeiro, Montevidio, Buenos Aires, and the chief ports in South Africa, Australia, Tasmania, the South Sea Islands, Japan, The Straits Settlements, India, Egypt and the Mediterranean.

It is expected that upwards of 150 British firms will be represented in the exhibition ship, which will contain every convenience for carrying on business, such as a secretariat, a reference library, writing rooms, in addition to first-class passenger accommodation for exhibitors' representatives. Cinematograph films depicting exhibitors' works and specialties will be shown at every port of call.

The proposed merger between several large and established machine tool houses in the United States has not gone through. The Lodge and Shipley Machine Tool Co., Cincinnati, Ohio, has made an announcement that it is not in any merger or combination, but will be operated independently as in the past, under the management of J. Wallace Carrel, vice-president and general manager. A similar announcement has been made by the Carlton Machine Tool Co., of Cincinnati. This company will continue to be operated independently under the management of Jack C. Carlton, president and general manager.

Machinery that "Stays Sold"

The fact that we carry the largest stock in Canada of new and re-manufactured machinery and supplies is an assurance that, whatever your need, we can fill it—promptly and exactly.

The fact that we handle only products of concerns of national standing; that our re-manufactured tools are not listed until they have been thoroughly re-fitted equal to new for all practical purposes, is an assurance of satisfaction.

The fact that our personal guarantee backs every sale and that we do not consider any transaction concluded until you are completely satisfied, is an assurance that you will "Stay Sold."

Our regular monthly Machinery List is full of bargains. Shall we put your name on our mailing list?

The A.R. Williams Machinery Co. Ltd.

Do You Read These Advertisements?

Every advertisement in this magazine is worth reading. It is the product of some concern that is using a modern method of making sales, viz., technical paper advertising, in order to present most effectively to you the leading features of its line.

These advertisers are making it easier for you to buy intelligently with the least waste of your time and theirs. They realize that a sales force can not replace this service at equal cost. They know that advertising is good business, for the manufacturer who does not advertise cannot save the cost of advertising. Consistent advertisers are progressive merchandisers. They are saving your money and their own; and it pays to do business with them.

Don't miss your opportunities. These advertisements are interesting. Many are distinctly instructive, and a glance through them every week will keep you posted on the latest developments for machinery equipment.

News From the Industrial Field

The contract for the $100,000 Church of the Sacred Heart to be built in Petite Cote, Ont., has been awarded to Benjamin Bondy of Chatham.

The Canadian Crocker Wheeler Co., St. Catharines, are in the market for a 7-ft. radial drill. Further details as to the style, type, etc., can be secured by writing direct.

Plans for the new St. Luke's Anglican Church to be erected at a cost of $40,000 are nearing completion. Tenders for the work of construction will be called May 15.

R. B. Crossby has been appointed superintendent of the Pembroke Woollen Mills. He comes from Scotland and has had considerable mill experience both in Canada and the old land.

The Sowards Coal Co. has purchased the steamer Brantford from Montreal parties and the vessel will be used in the coal carrying trade between Kingston and Oswego.

Anthony Morrison, a Bridgeport, N.S. young man, now claims, after several years of experimenting, to have succeeded in inventing an improved type of mining machine of great capabilities and a patent is now pending.

The Hydro Electric Power Co., of Ontario has commenced work on its new line on the St. Lawrence system between Morrisburg and Brockville. Work contemplated for this season includes also extension of the line from St. Mary's college to the village of Maitland.

A startling example of the high cost of freight is reported by J. C. Scofield of the Windsor, Ont., Lumber Co. This company paid $165.82 for a carload of lumber f.o.b. British Columbia. They paid the railroad $516.84 freight, over three times the value of the cargo.

C. H. Wothers, who was associated with the Canadian activities of Escher Wyss and Co., for nine years, and latterly with the General Supply Co. of Canada, will sail shortly for England, where he will join the London staff of Escher Wyss & Co.

Considerable damage was caused to the plant of Crowe's Iron Works at Guelph, Ont., last week, when fire wrecked one section of the main foundry building. No serious delay, however, will take place in the company's activities and repairs will be effected at once.

The possibility of a rate-war in regard to Trans-Atlantic shipping is expected in some quarters as a consequence to that now in effect in South American waters. Trans-Atlantic shipowners declare they were not anticipating reductions this spring, but may find it necessary to do so.

The Navy League reports encouraging progress in their drive to raise funds to establish a naval training station in Windsor, Ont. The station will be located at the foot of Bruce avenue on the Detroit River and will require about $5,000 to equip.

Opening of the Davidson lumber mill at Coulonge, Ont., has been delayed by the floods. Owing to the fact that about half of the year's cut was lost when the boom of logs broke on the Coulonge river last week the mill will run only three months this year instead of six as in normal years.

The cost of the new dairy school to be erected at Kingston, Ont., is estimated at between $80,000 and $90,000. The new building will be two stories in height and larger than the old school. It will be of modern construction and include an ice making plant.

Two churches of Windsor, Ont., are planning to build new edifices this summer. The Bruce Ave. Baptist church has purchased a site on Victoria ave. on which to erect a $125,000 building. The Knox Presbyterian Church has had preliminary plans drawn for a building to cost about $75,000.

Announcement is made of the appointment of C. D. Gleason to the position of Canadian sales manager for the Durant Motor Co., with headquarters at the Leaside plant at Toronto. Mr. Gleason, for some years has been associated with the Chevrolet Co. both in Canada and the United States.

The contract for construction of the intake and ship channel in connection with the Chippawa-Queenston power development has been let to the firm of Tomlinson, Macaw and McDonald of Winnipeg by the Hydro-Electric commission. It stipulates that the work must be completed by December 1st.

It has been stated that the directors of the recently organized Dominion Alloy Steel Co., have decided to enlarge their program to provide for the erection of a plant of $5,000,000 instead of the project originally contemplated, where the figure of $3.000,000 was mentioned. It is intimated that building operations will commence within two months.

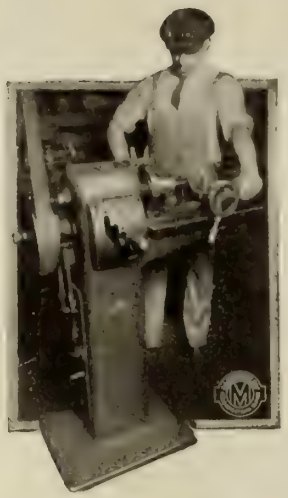
The council of Ford City, Ont., at its last meeting voted unanimously for the amalgamation of their town with Walkerville, the chief object being economy and facility in installing town improvements. If Walkerville adds the industries of Ford, such as the Ford Motor Co., the Fisher Body and Studebaker Corporations, etc., to those already there, which include the General Motors Ltd., Canadian Bridge Co., and Hiram Walker and Sons, it will be one of the principal industrial centers of Ontario.

A construction engineer of the Imperial Oil Co., is now at Sydney, N.S. to proceed with the construction of the Company's new plant at Battery Point. Some difference in the company's and the government survey of the lands deeded resulted in slight delay, but the difference has been adjusted.

Tenders are being received by the N. S. Provincial Highways Board up to May 4th for the establishment of a steam ferry service across the Strait of Canso between Port Mulgrave and Port Hawkesbury, capable of carrying not less than four large motor cars, and other traffic, with the necessary docking facilities.

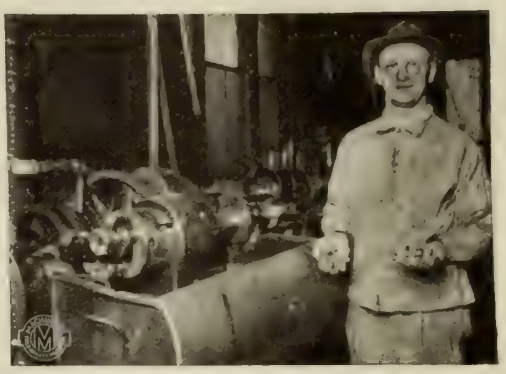
Dr. H. Deslauriers, (Member for St. Marys, Montreal), has given notice that he will bring before the Commons a resolution which would have the effect of prohibiting export of electrical power to the United States. The resolution will declare that "it is advisable to place a prohibitive duty on this anti-national commerce."

The Wettlaufer Co., machinery manufacturers, have started building operations on a site in the lower Kingston harbor, in accordance with their agreement with the corporation of the city of Kingston. Particulars as to general details of the building have not yet been issued. The work is at present under the charge of J. W. Lytton, contractor, of Kingston.



The Doran Construction Co. has been awarded three contracts by the Provincial Highways Commission. They will construct a large section of the new provincial highway near Cornwall. In addition, two contracts for bridges have been received for the Township of North Elmsley and Perth vicinity. Plans for the work have been completed and it will be started immediately.

The Halifax City Council has received the tenders for the contract of installation of new street electric lighting system. The city engineer, reporting on the tenders received, has recommended that of the Northern Electric Co., at $85,750.72. The contract under consideration is for lamps, standards, etc., and installation thereof, wiring already in use being utilized to a great extent, though in some districts underground cables are anticipated.



Peter O'Carroll, of Pictou, N. S., has devised a new pattern of ship's anchor and is having it patented. It is claimed that no matter how the anchor is cast it is bound to catch with both flukes. The bar through the top of the old style anchor is eliminated altogether and another feature claimed for the new pattern is that it is always easy to break the hold on bottom when the anchored craft is ready to move.

Considerable interest is centered in the progress of the new central heating plant for Queen's University and the Kingston General Hospital, which is being constructed on Kingston's beautiful harbor front on the site of the former Kingston Hosiery Co. mill. H. W. Watts, of Kingston, has the contract for the masonry. The large boilers have been placed in position and the first story is almost completed.

A request to alter the method of computing the tax on company earnings has been made to the Dominion Government by the Border Chamber of Commerce of Windsor, Ont. This body asks that the tax be figured on earnings over three year periods as it is done in the United States. By this method if a firm makes $100,000 one year and loses $50,000 during the next two it would be taxed on $50,000 only.

The Walsh Plate and Structural Works of Drummondville, Que., have secured the following contracts:—Structural steel for $500,000 factory for the Dominion Silk Dyeing & Finishing Co. of Drummondville; structural steel for new warehouse of Butterfly Hosiery Co. of Drummondville; new steel penstock for Rolland Paper Co., at St. Adele, Que.; steel for new theatre at Valleyfield, Que.; structural steel for new store on St. Denis St., Montreal.

At a meeting held on the evening of April 28, at the University of Toronto, Prof. McLennan gave an interesting talk on the metric system of weights and measures. Considerable interest was shown by the small number present, and at the close of the meeting initial steps were taken to form a Canadian Association for the purpose of studying the possibilities of the system and the advisability of promoting its adoption in Canadian commercial and industrial enterprise.

Capt. T. York, of Rockland, Ont., in conjunction with Russell J. Reaney, has perfected a machine that will revolutionize motive power. This is the claim of Earl York, son of the former. He states that the machine has been patented in Canada and the United States and that successful experiments have been made with it, power being generated from the air by some means which he further states will be demonstrated in Ottawa shortly. It is proposed to run a motor car here by this new force.

The plant and equipment of the Welland Machine and Foundries, at Welland, has been purchased by the Lackawanna Tubes, Ltd., and it will be remodeled to conform to the requirements of the new company. The principal activities carried on will be the manufacture of boiler tubes, and this will be a pioneer firm to produce seamless steel tubes in Canada. A new building, 80 by 400 feet, is now under construction. The old foundry, at present, will be utilized for general repair and foundry job work. The company is capitalized at $525,000.

C. V. Grantham of the Wallace Barnes Co., Hamilton, Ont., discussing conditions recently stated that he had found business to be improving. When asked in what particular industry he had noted most improvement, he stated that all industry with which he came in touch seemed to be brighter and this was borne out by the amount of orders actually received by his company.

Among the tenders for Halifax city supplies for the year recommended by the City Works Committee to the City Council for acceptance are the following: Six inch valves, T. McAvity & Son, St. John, N. B.; drain pipe, contract to be divided between Brookfield Bros. and Edgar Coombes & Co.; lead pipe, Geo. T. Hatfield and Wm. Stairs Son & Morrow, in five ton lots; corporation cocks, Empire Brass Manufacturing Co., Ont.; brick, Piercey Supply Co.; castings, Fleming Bros.; hardware, Lawrence Hardware Co. Ltd.; oils, Canadian Oil Co.; sand and gravel, Hendry & Co., Ltd.

At the coming conference of technical officers of the Empire Patent Office, to be held in London, Eng., in June, William J. Lynch, chief of the Canadian Patent Office, has been appointed to represent Canada. The suggestion for holding the conference was made in a memorandum prepared by the British Board of Trade on the desirability of instituting a patent which would be valid throughout the Empire. The late Government approved of the holding of the conference, subject to the provision that "while co-operation and uniformity are desirable, each constituent part of the Empire should retain within its own jurisdiction the control of the patent laws affecting it, and of their administration." The patent offices of Australia, New Zealand, South Africa, India and Great Britain, will be represented at the conference.

CANADIAN TRADE IMPROVES

The Wall Street Journal of April 28, in a general review of the exchange situation as it affects Canadian funds says: "Rise in value of Canadian funds during the past 15 months is due to several reasons. Rise of sterling exchange, and consequent increase of English buying in Canada has had a notable influence. England and the United States are Canada's two best customers and the relations of the three countries have been fast approaching normal. Canadian trade has shown distinct improvement. For 1921 there was a small export balance, which was unexpected at the beginning of the year. Since January Canada has had an import balance, although a small one. It has been estimated that April trade figures will show an export balance as grain shipments have been exceptionally large. The factor which has had probably the greatest influence has been Canada's capital imports. In 1921, out of financing which totalled about $400,000,000, about $182,000,000 was floated in United States, and $16,500,000 in England. Loans floated in the United States in 1919 and 1920, were even greater than in 1921. So far this year Canadian financing here has been in good volume, although Canadian bonds held here which mature this year total about $62,000,000, most of them are expected to be refunded."

FAVORABLE EXCHANGE RATE

While the discount on the Canadian dollar in the New York money market is not expected to hold at one and a fraction per cent. for any length of time, it is freely predicted that owing to the favorable position shown by Canadian finance, it will remain below three and one half per cent. for a considerable time. Canadian funds last week were at a discount of one per cent. in New York, the lowest rate touched since January 10, 1918, before which Canadian funds had sold at a premium in the market for a considerable period. The rate had risen as high as 17½ per cent. in February, 1920. During the remainder of 1920 the rate fluctuated between eight per cent. and 15 per cent. with the average nearer the later, but early in 1921 improvement in Canadian affairs and finances began, which has culminated in the present value. Since turn of the year the rate has at no time gone beyond 6½ per cent., and since February 1 the highest has been 4½ per cent. During the past five or six weeks there has been a narrow market. The $100,000,000 Dominion loan floated in the States recently was the direct cause of the new high Canadian funds.

C. P. R. DEDICATES WAR MEMORIALS

Simultaneously in several leading Canadian cities, and also in London, England, imposing and impressive ceremonies marked the unveiling of memorial tablets dedicated to the memory of employees of the C.P.R. company who were killed in the great war. At Windsor Station in Montreal, His Excellency Lord Byng, E. W. Beatty, president of the company, and many other officials were present. In Toronto, the brass tablet was unveiled in the main waiting room of the North Yonge St. Station. At West Toronto the bronze tablet is located on the front facade of the depot building. Among other places where ceremonies were conducted were North Bay, Winnipeg and Vancouver.

BOOK REVIEW

The "Coal Manual" is the title of a book issued by the National Coal Mining News, Cincinnati, which deals with coal from all the aspects which are of use to a purchaser and user of this universal fuel. In addition to chapters on the analysis of coal, other chapters deal with the efficient burning of coal, and there are instructions to firemen and engineers. The book, which is published at $2.50 in the U. S., should be a valuable one for purchasing agents, plant managers, and engineers in general.

ATKINS
METAL CUTTING SAWS

Solve your Metal Cutting problems, easily, quickly and economically, by adopting the products made by

ATKINS

We make Kwik-Kut Power Hack Saw Machines which use practically the full cutting edge of the Hack Saw Blade at each stroke; Metal Cutting Band Saw Machines for general shop work, cutting all classes of metal up to 12 x 14 inches.

Your requirements for Metal Cutting Circular Saws can be supplied promptly and we solicit a trial of our "AAA" Non-Breakable and Power Hack Saw Blades and Frames.

Factory: HAMILTON, ONT. *Branch:* VANCOUVER, B.C.

INDUSTRIAL ACTIVITY IN FORT WILLIAM DISTRICT

Preliminary work is well under way in the construction of an additional traveling coal handling bridge at the Island Number One coal dock of the Canadian Pacific Railway. The work is being done by the McMayler Interstate Construction company, of Cleveland, and will involve an expenditure of over half a million dollars. Most of the material for the structure has arrived and the actual fabrication of the steel will commence within a few days. The bridge, when completed, will greatly increase the efficiency and storage capacity of the plant.

The last of the sixteen hundred piles for the new Parrish and Heimbecker grain elevator being erected in the Port Arthur harbor, just south of the Canadian Government elevator, was driven early this week and sheet piling is now being sunk for the wharf. The first unit of the elevator will consist of a working house and six concrete storage tanks with a total capacity of 250,000 bushels. Arrangements are being made in the building of the foundations for extensions as the ultimate intention is to enlarge the plant to a house of one million capacity. The elevator will be finished it is expected, in time to assist with the 1922 crop and will be equipped with the most modern apparatus for the treatment of off-grade grain. J. W. Cook, superintendent of construction for the Canadian Stewart Company, Chicago, who are building the elevator, is supervising the work and will spend the summer here.

Much material is being assembled by the Canadian National railways upon the site of their new yards, extending from a point just within the westerly limits of Fort William, to a point about five miles west, and construction of the yards will commence immediately. The new yard will contain, besides tracks for many thousands of cars, roundhoses, repair shops and offices, and residential quarters for the staff. Plans call for the tearing up of the present Canadian government railway spur running from Fort William to Dona, about thirty miles as traffic over both the Canadian government railway and the Canadian National will be diverted through the new yards of the latter.

Construction will be commenced within a few days by the city of Fort William, upon the mile and a third street railway extension running from the Mission industrial extension to the newly opened up municipal park, west of the Mission industrial sites. Plans call for not only the laying of steel but the construction of a highway.

On April 24 the plant of the Consolidated Water-Power company's mill, formerly known as the Kaministiquia Paper Company's mill, at Port Arthur. commenced running double twelve-hour shifts. Nearly forty men are being employed continuously and it is expected that the output will reach a carload of ground pulp per day. It is being shipped to Wisconsin Rapids.

Continuous operation still continues at the Mission plant of the Fort William Company and the output of the plant has reached 120 tons of dry pulp per day. The company, during the winter has bought the output of many pulpwood camps situated along the upper reaches of the Kaministiquia river, and as soon as water conditions are favorable, the wood will be driven down stream to Thunder Bay. Some 41,000 cords are boomed at Dona, thirty miles up. The drive will be the largest of its kind ever undertaken in this district and will be especially hazardous as the wood must be shot over Kakebeka Falls, one hundred and forty-six feet high.

Geo. A. Benson, superintendent of the Fort William Coal Dock Co., since the erection of the big dock at the Mission, several years ago, has severed his connection with the firm and has left for the United States. L. Savage, of Cleveland, has been appointed superintendent.

Chas. L. Jobb, manager Canada Iron Foundries, in the city last week from Montreal, in connection with the company's local foundry, declared that business outlook was not particularly encouraging. The plant is operating about three quarters capacity upon the manufacture of iron pipe and car wheels, some of which were to be used in filling orders and some would be placed in stock.

F. H. Palmer, junior trade commissioner, commercial intelligence service, department of trade and commerce, Ottawa, was a visitor in the city recently for the purpose of acquiring information respecting local industries and the operation of grain elevators and the system of handling grain generally. He was given valuable assistance by Leslie Boyd, chief commissioner, board of grain commisisoners of Canada, and other officials of the grain controlling and inspection staffs.

Judgment has been handed out in connection with the case between the Motor Trucks, Ltd., of Brantford, Ont., and the United States government. The buildings, valued at $343,000 were first awarded to the U. S. but the appeal court has decided that these are the property of the Motor Truck Co. The United States of America put $1,900,000 into the plant of Motor Trucks, Limited, Brantford, for the purpose of having high-explosive shells manufactured there for the war. The company dropped all its other activities and bought four acres of land for extending its factory. Then, before a single shell had been manufactured, the contract was terminated.

A certain number of accidents involving injury to the eye are unavoidable. The presence or absence of permanently detrimental results is likely to depend on the promptness and efficiency of the treatment that is instituted.

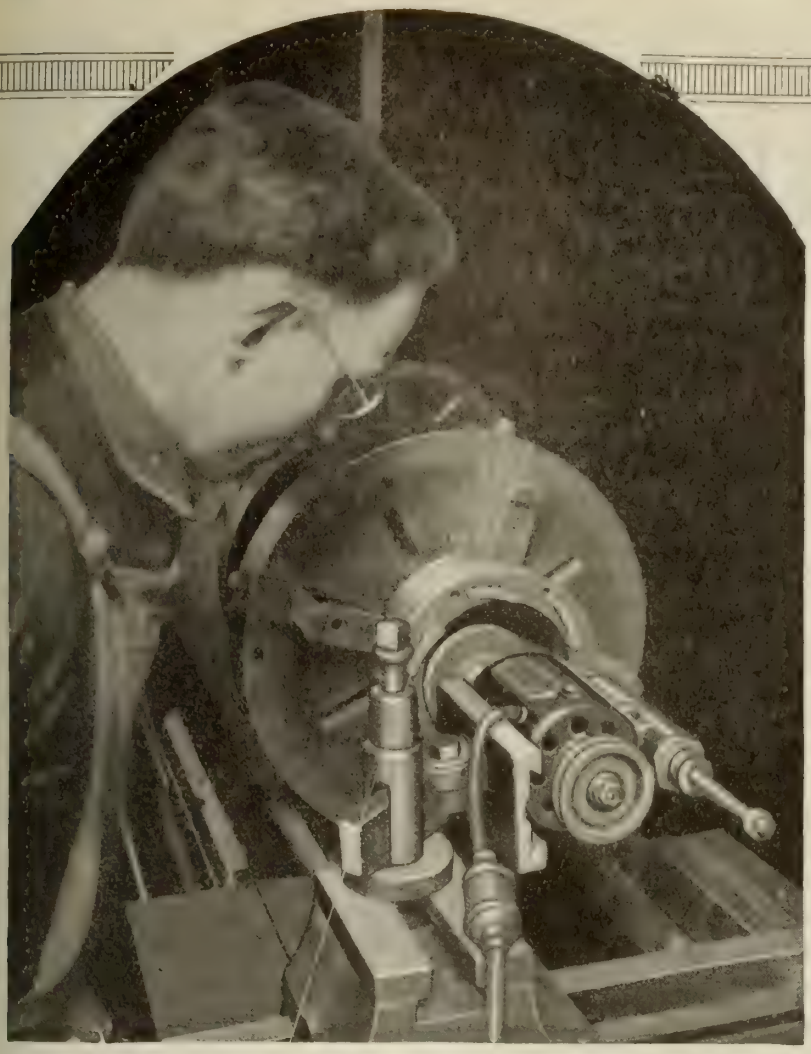
Tomlinson, Macaw & Macdonald, of Winnipeg, have secured the contract for the intake on the Queenston-Chippawa power devlopment. The estimated cost of the work approximates $450,000.

The dredging work on the Welland River, in connection with power developopment of the Hydro-electric Power Commission, will be undertaken by Lachay & Co., the cost of the work being about $500,000.

OBITUARY

L. S. Starrett

Leroy S. Starrett, philanthropist, inventor and founder and president of the L. S. Starrett Co., manufacturers of Starrett tools at Athol, Mass., died April 23 at St. Petersburg, Florida, where he had been spending the winter months, as had been his custom for a number of years. Had Mr. Starrett lived two days longer he would have been 86 years old. In addition to his connection with the L. S. Starrett Co., Mr. Starrett was treasurer and practically the owner of the Athol Machine Co., and was interested financially in the Union Twist Drill Co. Born in China, Me., April 25, 1836, he was of Scotch descent and one of 12 children of Daniel D. and Anna Starrett. When only 17, he operated a farm of 600 acres in Newburyport. At that time his inventive genius was developing rapidly, and in 1864 he was granted a number of patents, and opened a machine shop in Newburyport.



In 1868 he came to Athol, where he combined his business with the Athol Machine Co. in order to manufacture his own inventions. Prominent among them was a meat chopper. For 10 years he was general agent and superintendent of the concern, then resigned to begin manufacturing mechanical tools.

Joseph P. Rogers

E. P. Rogers, director of the Queen City Oil Co., died last week at his home in Toronto. The late Mr. Rogers was born in King Township, North York, October 17, 1856, and received his early education in Newmarket High School and Earlham College, Richmond, Indiana. He came to Toronto in 1876, and shortly afterward entered into business with his father, the late Samuel Rogers, and his brother, Mr. A. S. Rogers, under the firm name of Samuel Rogers and Company, and later under the name of the Queen City Oil Company Ltd. He was manager of the lubricating department at the time of his death, and was also a director of the Imperial Oil Co.

Matthew Stanley

The death occurred last week of Matthew Stanley, following a long illness. He was a mechanical engineer, and in that capacity had been connected with the Northern Aluminum Company prior to his retirement some five years ago. Before coming to Toronto Mr. Stanley had been with Vickers Limited in London, England.

At the left is shown a DUMORE grinder attached to the toolpost of an engine lathe at the Geometric Tool Co., New Haven, Conn. A cam for a die lead has been just machined and the hole is being accurately ground without tearing down of the original "set up." Result—faster work at a decreased operating cost.

Thousands Now in Use —*a tribute to* DUMORE *efficiency*

A FEW years ago the DUMORE line of high-speed grinders were new devices on the mechanical market. But to-day thousands of these better grinders have found their way into the tool rooms of the leading industries of the nation.

The many thousands of DUMORE grinders now in active service—their endorsement by the world's foremost mechanical experts — the numerous re-orders, *all* are tributes to the efficiency of DUMORE grinders more forceful than any other we know.

DUMORE grinders can meet *your* requirements for intricate grinding work as they have met the needs of over five thousand other industrial leaders. Set them up anywhere—use them for varied kinds of grinding. You'll find them equal to the task—performing swiftly, smoothly and accurately.

Be assured of correct cutting speed with a range of 10,000 to 30,000 R.P.M.—get accurate grinding to limits of .0001″—eliminate the costly need of tearing down original "set-ups." Put one or more of the DUMORE grinder family in your tool room!

Write to-day for complete information and descriptive literature—let your dealer demonstrate.

When Stephen Leacock Met the King

"It was on the G. T. R. platform in Orillia, Ontario, when he was Duke of York....No doubt he would recall it in a minute....Bob Curran—Bob was Mayor that year—went up to him and shook hands and invited him up to the Orillia House, where he had a room reserved for him. George Rapley, the bank manager, said that if he wanted a cheque cashed or anything of that sort to come right into the Royal Bank and he would do it for him. The prince had two aides-de-camp with him and a secretary, but Bob Curran said to bring them uptown, too, and it would be alright. We had planned to have an oyster supper for the Prince at Jim Smith's hotel and then take him either to the Y. M. C. A. pool room or else over to the tea social in the basement of the Presbyterian Church. Unluckily the prince couldn't stay. It turned out that he had to get right back into his train and go on to Peterborough, Ontario, where they were to have a brass band to meet him, which naturally he didn't want to miss." In the

TRAFFIC—
a science in itself

Only the institution operating on a major scale can maintain that type of fully-manned, thoroughly-experienced Traffic Department which best guards a buyer from shipping delays, needless freight charges and interruption of production-schedules. It is more than a man-sized responsibility—it is an organization-sized job for a specialized staff such as M. A. Hanna & Co. maintain at all times.

DIAMOND SAW & STAMPING WORKS -:- BUFFALO, N.Y., U.S.A.

This Boy Gets Big Production

He is Using the

"Procunier"

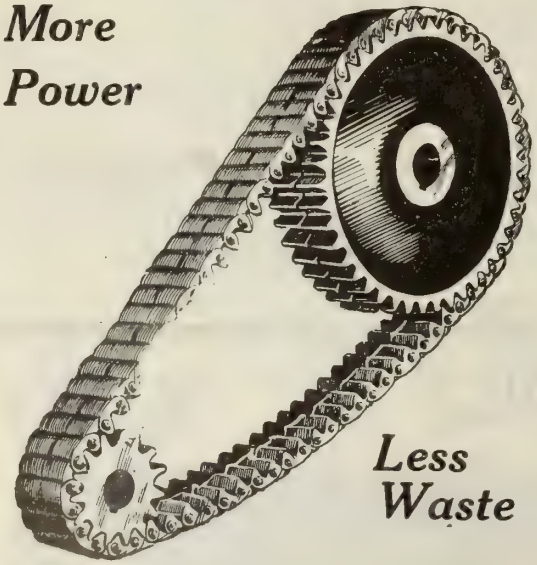
Safety Tapping Attachment

The boy is seen tapping ¼" open hearth steel couplings for a magnet drive with a 5-16"-18 thread. This is short cutting production! There are 16 holes in each piece and like all work of this class it must be accurate. The boy shoves the work right along—one completed piece every 80 seconds, 720 holes per hour.

720 Holes Per Hour

Send for More Information

The "PROCUNIER" Safety Tapping Attachment reverses at twice its forward speed. Equipped with Safety Friction and balanced reversing mechanism that eliminates all torsion. Cut your costs with our Tapping Attachments, Safety Tapping Chucks and Tap Holders, which are all equipped with a patented "DOUBLE-JAW" Chuck. **Ask for facts and figures.**



WILLIAM L. PROCUNIER, 18 South Clinton Street, Chicago, Ill.

RENOLD

SILENT CHAIN DRIVE

More Power

Less Waste

The Recognized Standard for Efficient Power Transmission

Twenty-six years' highly efficient performance in the finest plants in the country has built up an enviable reputation for Renold Silent Chain Drives. Absolute reliability in service with maximum efficiency and minimum maintenance costs has made "Renold" the universal name for power transmission chains. Renold Silent Chain Drives are applicable to any powers, no matter how small or large and not only are they silent in operation, but also unaffected by heat, cold or moisture.

Let Renold Chains solve YOUR power transmission problems, and ensure YOU maximum efficiency, durability and service. Our engineering service is at your disposal without obligation. Why not write us?

KAELIN ELECTRIC STEAM GENERATORS

Their Field

Any mill or factory developing its own power which has surplus electric energy during the whole or any considerable part of the day.

Any mill or factory operating on bought power purchased on a "flat rate" basis, but which is not using all the power allotted to it.

Capacities

These Electric Steam Generators are built in sizes from 600 to 25,000 K.W., corresponding approximately to 60 to 2,500 Boiler horsepower.

They can be operated by alternating current only, and are built for voltages varying from 550 to 12,000.

Advantages

Their first cost including installation is low compared with any type of coal or oil-fired boiler plant.

They are safe, clean, easily regulated, require but little attendance and take up very small floor space.

They can be operated in parallel with existing boilers or can be installed close to their work.

Information and prices promptly submitted on receipt of particulars as to your conditions.

"The PHOTOSTAT is Largely Responsible for that Increase in Sales."

"WHEN we installed the PHOTOSTAT, I saw that it could be made of invaluable service to the sales department. At our last meeting all the salesmen said that the PHOTOSTAT copies of the engineering data sheets, the testimonial letters and our rush bulletins closed many an order for them. And they remarked especially about the convenient form in which the data came to them.

"I've been taking typewritten matter, clippings from trade papers and illustrations from various sources—combining them on one sheet and reducing them to a standard size on the PHOTOSTAT. These standard sheets fit into the sales books and are easy to refer to. Before, the salesmen had sheets of so many different sizes that they quickly lost track of most of them.

"The advertising department also told me today that the PHOTOSTAT has reduced the time spent on layouts in that department by 50 per cent.

"Of course, we all know how much the machine has speeded up our production. Just mention the PHOTOSTAT to our shop superintendent or our chief draftsman and you will see a satisfied smile."

The PHOTOSTAT makes no mistakes. It makes Photographic facsimiles directly on sensitized paper.

It will copy blueprints as well as tracings or pencil sketches; even small machine parts; thus eliminating much tracing work in the drafting room. It copies in a few minutes and without error subjects which it would take hours or even days to copy by other methods.

In the office the PHOTOSTAT eliminates the mechanical drudgery of copying by typewriter or longhand. It copies letters, telegrams, reports, graphs, charts, shipping lists, contracts, ledger pages, insurance records, legal documents. The PHOTOSTAT copies do not have to be read back for errors or checked with the original. You know they are right.

In our booklet, "A Good Word For the PHOTOSTAT" many companies in widely different industries tell of savings which the PHOTOSTAT has made for them. Send for it.

Buried in the Work and Broke!

Next time a tap breaks below the surface of a large casting, don't let some makeshift method of removing it injure the thread and waste half an hour of valuable production time. Instead—

Walton it Out in a Jiffy

And save the casting.

Special analysis steel fingers of the Walton Extractor drop into the flutes of the broken tap—and grip. Then a few turns of a wrench applied to the squared end of the Extractor backs out the buried tap.

Sixty-day trial offer proves the Walton Extractor pays for itself. Write.

The Walton Co.
Hartford, Conn.

A HOIST THAT WON'T WORK

Have You One?

It may have been abused by overloading or careless handling.

It may have "worn out" after years of faithful service.

You will probably need it soon.

Ship it to us. Our repair department will quote for the necessary repairs, even if the block is not one of our own make.

If it is a Morris hoist the cost of repairs will be comparatively small — Morris hoists are so designed that the wearing parts may be replaced readily.

Of course we test all rebuilt hoists with our usual 50% overload test before shipment.

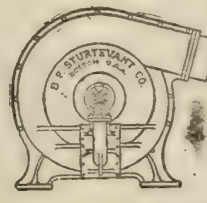
Collecting Dangerous Dust Conveying Useful Material

The satisfactory disposal of dust, caused in many manufacturing processes, is always a problem.



Whether in a pattern shop or grain elevator, dust is a nuisance and a recognized menace to life and property.

With over sixty years' experience at the back of them, Sturtevant engineers are called upon, almost daily, to solve dust-collecting problems in scores of different industries.

Or, it may be that light material must be conveyed from place to place. In a certain woolen mill, for instance, the wool is never touched by hand from picker to cards. Grain, fuel, bark, etc., etc., may be similarly conveyed.

If you wish to improve working conditions, lessen fire risk, or cut the cost of handling material, ask our engineers to call—without the slightest obligation to you.

Write for the new Bulletin on Collecting and Conveying, No. 291.

ARMSTRONG
Standard Ratchet Drill

Use It— Where Others Are Useless

In many cases the flexibility of the Armstrong "Standard" Ratchet Drill will save the delay and expense of disconnecting and dismounting heavy machinery and repay its cost many times over.

Some of the difficult situations where this tool will be found indispensable, paying for itself many times on a single job, are:

Confined places in setting up new work.
Drilling and tapping pipes.
Repairing boilers and steam pumps.
Locomotive and heavy machinery repairs.
Repairs on board ship..

Simple Construction

The Armstrong "Standard" Ratchet Drill has no ball joints or bevel gears. It is simple in construction, made from drop forgings and bar steel with all working parts hardened. It drills 10 per cent. faster than an ordinary ratchet — two inches of motion at end of handle, in any direction, will drive the drill.

A Complete Line of Ratchets

The Armstrong Line of Ratchet Drills covers the field completely and is the only one that does. We offer our trade a Ratchet to meet the peculiar needs of any kind or condition of work. Write for catalogue.

DIRECTORY OF DEALERS

THE Buyers' Directory of CANADIAN MACHINERY was originally intended to contain information regarding lines actually manufactured by our advertisers. We now carry the advertising of leading machinery dealers, some of whom represent scores of manufacturers in addition to being manufacturers themselves in some cases. We recommend, therefore, if our subscribers cannot find what they want in our Directory that they communicate with the dealers whose names appear herewith.

LiftAbout with yoke attachment for handling small parts in cans. Used by Hyatt Roller Bearing Co.

THE SHEPARD ELECTRIC LIFTABOUT

Low cost load moving

now when most needed

The **LiftAbout method** for lifting, carrying, and putting down loads could not be offered at a more opportune time than **right now,** when everybody in every business is "weeding out" inefficiency, and slashing overhead costs.

This small, but powerful, electric hoist was designed so every business, small as well as large, could enjoy the advantages and economies of power lifting—and because it provides a faster, safer, and cheaper way for load-moving and lifting, it is to-day being applied in practically every line of business.

With a **LiftAbout**, one man in a systematic orderly way can do the work of many. He can handle loads of every type and proportion in capacities to 2,000 pounds.

A **LiftAbout** is easily and quickly installed and runs on overhead I-beam track, taking up no valuable floor space. It is surprisingly low in price, and negligible in upkeep. Has same principles of design and construction that have made "Shepards" America's best known and largest used electric hoists. Permit us to demonstrate **LiftAbout** economies for your work. Drop us a line to-day.

Distributors being selected—Write.

Shepard builds electric cranes and hoists in capacities to 30 tons.

PETRIE FILLS THE BILL

THE tremendous stock of machinery and supplies of all kinds at the Petrie warehouse (more than 130,000 square feet of floor space) is an assurance that, whatever your requirement, it can be filled.

The Petrie service—prompt, efficient and embracing a staff of experts who are at your command at all times as advisors on your shop problems—is an assurance of your continued satisfaction.

Together, these factors have established Petrie's as

Representing the Leading Manufacturers

In addition to manufacturing and distributing Fairbanks-Morse products, The Canadian Fairbanks-Morse Co., Limited, represents the leading manufacturers of mechanical goods.

When ordering from our nearest branch, you are ordering from the manufacturer whose product has proved itself the acknowledged leader in its particular field. Here are some of the well known lines we handle:—

Fairbanks Valves
Brown & Sharpe Machine Tools
McDougall Lathes
Gisholt Turret Lathes
South Bend Engine Lathes
Landis Threaders
Graton & Knight Leather Belting
Yale Chain Hoists
Esterbrook-Allcard High Speed Drills
Norton Grinding Wheels
Dick's Balata Belting
Fairbanks-Morse Motors
Durabla Packing

Each department is in charge of men who can give you valuable help in the solution of your problems.

—and constant operation isn't the only feature of this Hepburn Pump!

Patent Feed Pump

OF COURSE to keep costs down constant operation is essential. The Hepburn Patent Feed Pump reduces costs still lower by constant EFFICIENT operation. Long strokes; self-draining cylinders; accessible valves and other features insure maximum production. Why not see us about Pumps, Engines, Winches, Compressors, Cranes, etc?

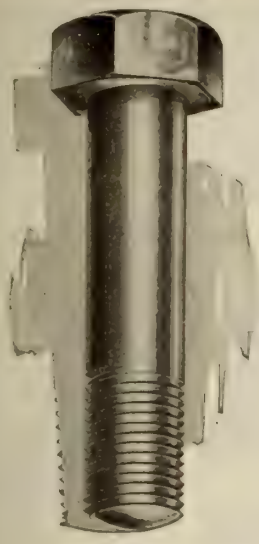
JOHN T. HEPBURN, LIMITED
Engineers and Iron Founders
18-60 VAN HORNE ST., TORONTO, ONT.

Filtration of Oil Saves Power

Faulty lubrication means loss of power on each of thousands of bearings in your plant. Fuel must be burned and current used which *gives no return for its cost.*

Perfect lubrication necessitates clean oil. Filtration is the only means of cleaning oil and conserving its full lubricating quality.

Bowser Oil Filtering Systems do this by removing all water and dirt from your oil. The same oil can be used indefinitely—and will always give the same clean, cool lubrication.



The Bowser Systems save the cost of fuel consumed in generating that wasted power, lessen machinery depreciation by reducing friction and cut your oil bill in half.

Ask Bowser Lubrication Engineers.

Increase the Consumer's Interest

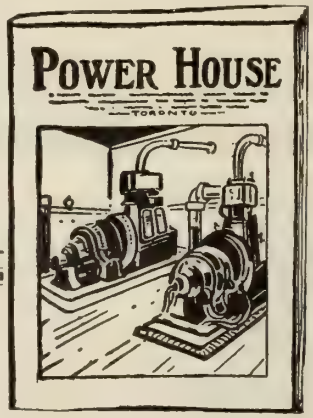
Create a Livelier Demand for Machine Shop, Power House and Foundry Equipment

ARE you manufacturing equipment for Machine Shops, Metal Working Plants, Power Plants and Foundries? Does the consumer know your products? Does he know their quality sufficiently to insist upon getting them when he places an order with his hardware dealer? Carefully weigh these questions. Then consider the advisability of reaching the consumer through the columns of MacLean Technical Newspapers. You can probably use one of the following group.

CANADIAN MACHINERY AND MANUFACTURING NEWS—issued weekly, serving the Canadian Machinery, iron, steel and general metal-working industries: it is read by the men who buy equipment, proprietors, purchasing agents and other executives; its editorial contents are authoritative and comprehensive.

POWER HOUSE—published twice a month, serving steam, electrical, water and gas power plants, in addition to refrigeration plants, in all parts of Canada. It, too, reaches the men who buy equipment; it, too, is the leading authority of the Dominion in things pertaining to its field.

CANADIAN FOUNDRYMAN AND METAL INDUSTRY NEWS—published monthly, rendering indispensable service to the grey iron, steel and non-ferrous foundries of the country. Proprietors, executives and foremen read it diligently.



You can awaken new interest in your products by advertising them to the consumer through MacLean Technical Newspapers. Write for complete information.

You pay your workmen well for their time and effort: don't waste this labor-element by keeping dull files in use.

A file ceases to be fully efficient as soon as it has begun to lose its keen-cutting edge. Replacing it costs only a trifle but means much in increased efficiency.

These brands, the standard for over fifty years, do not dull quickly:—

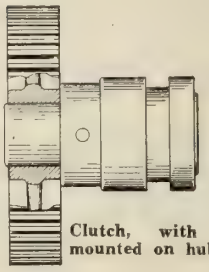
THE JOHNSON FRICTION CLUTCH

IS USED ON THE

PEERLESS DOUGH MIXER



Courtesy of the Peerless Bread Machine Co., Sydney, O.

A No. 4 single clutch is used to facilitate starting and stopping.

Lubrication is a necessity for all running bearings and frictions and an occasional application is all that is necessary.

Adjustment of the Johnson friction clutch is simple. A small screw moves two taper blocks in toggle levers, giving greater expansion to ring — thus more gripping power.

Clutch, with gear mounted on hub.

The Johnson friction clutch is a small, compact and very powerful device for machinery of all kinds where medium or light power is transmitted.

DUNLOP BELTING

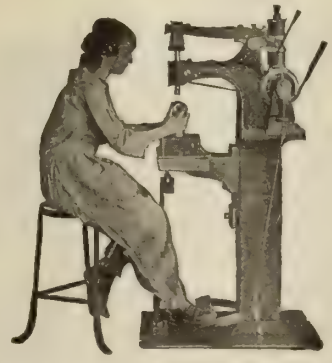
---FOR---

Maximum Power, Speed and Service

Unlimited capacity for hard, fast service is the feature of Dunlop "Gibraltar RedSpecial" Belting.

The success of over a quarter of a century in the manufacture of Rubber Products is built into Gibraltar.

As the original Made-in-Canada Red Rubber, Frictioned Surface Belting, it has stood the test of time in turning the wheels of industry in a multitude of-belt-using plants from the Atlantic to the Pacific.



In buying "Gibraltar RedSpecial" Belting you get the advantage of years of careful laboratory work on our part with this result: The friction is of that "just-right" elastic quality which allows for the give and take necessary in rounding the pulleys; hence the reason "Gibraltar RedSpecial" is known for Maximum Power, Speed and Service.

The Lion and The Mouse

DO YOU remember reading in the school books about the great big lion who was caught and trapped in a gigantic net by hunters? Then along came the little teeny mouse who nibbled away at the netting and was successful in setting the lion at liberty again. The net was too strong for the lion to break but the constant nibbling of the mouse, breaking mesh after mesh, was able to perform the seemingly impossible.

A person who is not subscribing to CANADIAN MACHINERY is in exactly the same circumstances as the lion imprisoned in a corner—not being able to enjoy the freedom of expanding his capacity for knowledge.

CANADIAN MACHINERY acts as the mouse. Week by week it will give information—which, on account of the lack of it, has tied you up in an industrial way—will nibble away the meshes, one at a time, that are keeping you from getting the results you want.

Ask us to send you a sample copy. It will not obligate you and it will be a pleasure to us.

CANADIAN MACHINERY,
143 University Ave.,
Toronto, Canada.

Screw Driver No. 570

A new and very practical screw driver for tool-makers, machinists and general use. With its three blades of different sizes, this screw driver can be effectively used in driving nearly all screw heads. A knurled nut and specially designed tang holds the blade firmly in position, enabling it to withstand the greatest leverage.

The hexagonal handle affords an excellent grip, an advantage that will be appreciated by all who have much occasion to drive screws. Consult page 298 in the Starrett Catalog No. **223** for description and illustration of this new Starrett screw driver. If you have no copy handy, write for one. Sent free on request.

Construction of Adapters for Turret Lathe Tools

Nature of Work Will Determine the Best Type to Use—Method of Holding and Adjusting Shanked Boring Tools—Floating Adapters for Specific Purposes

By FRED HORNER

AMONG the numerous problems which confront the designer and the tool-maker in tooling up turrets one of the most important is that of arranging the holding devices. This is not always a simple matter, especially in regard to the larger turrets. Diameters and shapes of tools, or of their shanks, vary considerably, and the lengths of projection are extremely diverse in some examples. All these things have to be considered in laying out the equipment, and special fittings may require to be made. Some of the tools go direct into the turret holes, and entail no further difficulty; others must have bushings, or brackets, or bars, or holders to provide the necessary accommodation. The purpose of the present article is to consider how these various adapters are made and arranged in different circumstances, with a few illustrations of the more typical specimens. Some are standard details, supplied by the turret lathe makers, but many need to be made up in the shop.

Until the nature of each job is examined, tooling diameters and lengths considered, and the apportioning of the operations throughout, the tool-designer is unable to say what kind of adapters may be wanted. The size and functions of the cross-slide or carriage have a partial influence upon this problem, for on the one hand there may be certain operations done from the slide instead of from the turret—which fact affects the design of some tool holders in the turret—and on the other hand requirements of turret clearance over the slide and between its front and rear holders may involve longer tools, or specific adapters. Also, if cross-slide operations proceed simultaneously with turret cuts, this will often necessitate longer projection of the turret tools, or some alteration in the mode of their holding. The chief instances where all these variable factors do not worry the designer are those of simple sets of short tools, not subject to interference with the cross-slide outfit. It is feasible then even to abolish adapter bushings, and make the shank of every tool, whether centering, starting, facing, drilling, counter-boring, turning, chamfering, etc. of uniform size to match the turret holes.

Simple Adapter Bushes

The elementary duty of providing a fit for a smaller or larger diameter of tool shank to the standard turret hole necessitates a bush bored smaller to suit, or enlarged into a hood, or sometimes flanged. Similar conditions prevail when the desire is to hold a tool out to a certain distance, its shank (which may or may not be of turret hole size) lying in an extension adapter. If the type of tool shank permits, a simple split bush, A, Fig. 1, or with knurled flange, and three cuts, B, is suitable; the grip of the binder bolt then serves to secure bush and tool shank. The shape of the last-named may, however, require something different from a parallel round hole, such as if a taper shank has to be carried, or a tool is made from flat stock. In the first case a solid adapter with taper bore and extracting slot, C, answers requirements, and a slotted bush, D, accommodates the second. The hood form of adapter is usually a simple enlargement to hold the extra diameter, with a screw or screws to bind the tool shank or body. To gain exact alignment of certain tools, the adapter can be flanged, and attached by screws to the hood (such as at E). Or if a loose floating action happens to be appropriate for the tool concerned, the hood can be fitted suitably into the turret bush, F.

For extra projection of a tool the best plan lies in the use of a bushing with split grip at its outer extremity, if arrangements for fitting various sizes of tool shanks are desirable; one of a set

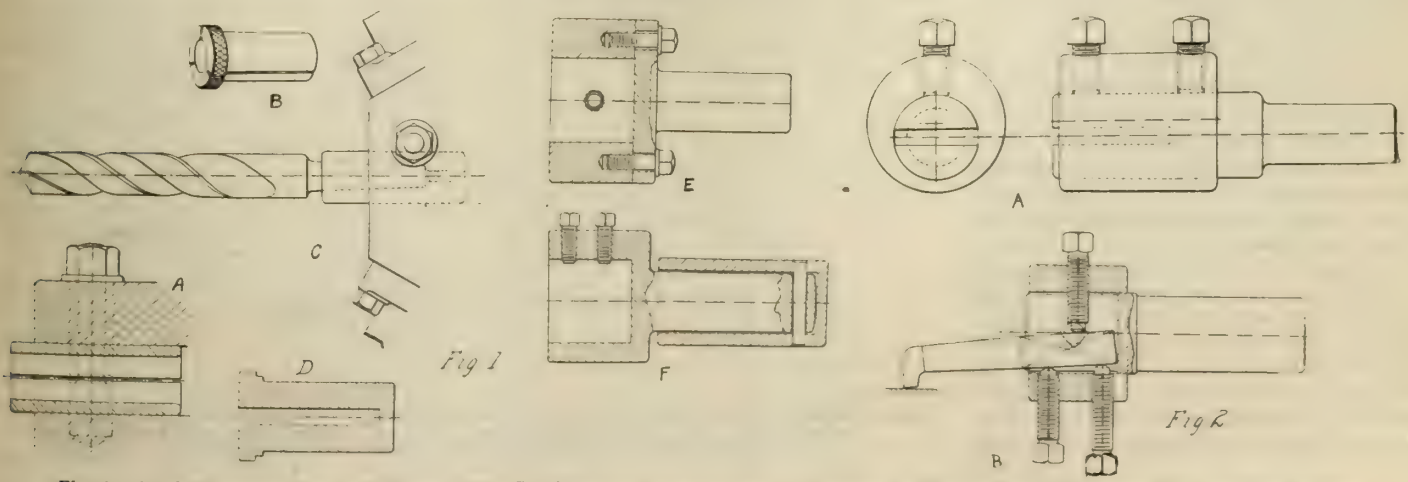

Fig. 1.—A, plain adapter bush, with three splits, C, adapter for taper shank. D, adapter for flat section. E, adapter with centering adjustment. F, with floating action. Fig. 2.—A, adapter for projecting flat shanks from turret, B, for holding square shank tools.

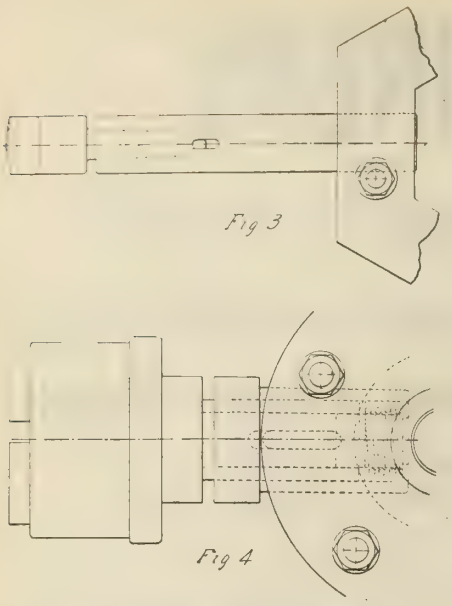

Fig. 3.—Long bar type of adapter.
Fig. 4.—Adapter with spring fitting.

of loose split bushings in the hood then receives the shank. When frequent substitutions of standard tools become necessary during the operations, a regular drill chuck actuated with key offers a more convenient solution of the problem.

With regard to flat shanks, which are either too wide to go into a turret bush, or must be extended further than such permits, a favored device embodies a slot in the lengthened body, and an encircling bush, Fig. 2, A, provided with screws for compression. Should different widths of stuff have to be gripped, side screws may be added to press on the edges, a similar principle being adopted when precise centering becomes necessary. Fig. T, B, illustrates a special modification made by Warner & Swasey for the purpose of holding and adjusting shanked boring tools. After setting the square shank to the angle and boring size required, with the manipulation of the three screws seen, it is firmly clamped by a side screw (shown dotted) which passes through the encircling collar and contracts the split end of the bush.

Extra projection of taper-shank tools turns the adapter into a shape like that in Fig. 3. Necessity for tool-steel economies explains the employment of many such extension bars, carrying only perhaps a bit of a tool on the nose. Such a long extension is essential to bring the tool end out to approximately the same distance as the other tools in the set. It never pays to make such a length wholly of tool steel, excepting in those circumstances which demand long fluted drills that are not conveniently fashioned with loose tips fitted in.

Delicacy of endlong adjustment occasionally modifies the particular requirements of an adapter, into the design of which a knurled nut is incorporated, with a fine thread to adjust the tool outwards in relation to the turret, until an exact depth of penetration into the work is attained. Or the relations of two tools held by an adapter are modified until the respective depths of recesses, or distances of shoulders, etc., receive their final and exact correction. A sample of such adjustment obtained in another manner will be shown in a subsequent figure.

Floating action in adapters has already been mentioned, and there exists another class of freedom provided in some circumstances, chiefly to screwing dies. If these are worked in a turret moved by cam action, a spring connection may be arranged, with a key, as shown in Fig. 4, whereby the die shank is allowed to yield slightly. Exact leading by the cam, a matter of difficulty to arrange, is thus not necessary.

Dual-Purpose Adapters

Tooling demands largely introduce extensions on to adapters, to fit them for conducting more than one operation. To select a simple example, the addition of an arm to the bushing, Fig. 5 presents a turning tool that cuts a certain length of body meanwhile the drill pinched in the adapter hole performs its duty. More complicated outfits incorporate three or four tools acting on diameters, or shoulders or bevels.

Adapter Brackets

We now come to an extensive class of adapters, utilised for turrets other than those of small sizes. The distance to which the tools must have their ends brought from the turret face, and the severity of the cuts imposed on some of them, necessitates stiff brackets that represent the bushings of the small turrets. Some of these brackets nevertheless often carry insignificant tools, such as those for centering, small drilling, etc; it is cheaper to leave the brackets in place and fit suitable adapters. Perhaps the next job may involve heavy-cutting tools in nearly every station. A further fact is that the importance of securing alignment of the tools, whether large or small, renders the provision of stiff adapter brackets essential, for an unduly long bar of comparatively small diameter would not always ensure satisfaction, nor perhaps withstand constant use with flexing. Moreover some of the tools have shanks which need a strong clamp device to hold them properly, and this is best afforded by a powerful bolt in the socket of the adapter. Such a fastening is more convenient and less damaging than using a cotter passed through the adapter and bar, and avoids the trouble of slotting the bars. When the turning effort on the bar is sufficiently strong to render a key necessary, a spline may be cut on the bar shank and a loose key be dropped in, or a cross slot and tongue coupling be used, but for a large number of tools the friction grip is ample.

Two requirements for a good adapter bracket are a well-spread base, firmly bolted to the turret face, and a spigot joint for centering. In dealing with cuts that demand a floating tool—piloted or not—the adapter, or its bushing is modified to give the requisite freedom. Other special arrangements include the facility for rapidly inter-changing different tools in one adapter (when a large number of operations have to be done from the turret); and means for giving a delicate feed to fine tools with an auxiliary rack mechanism, where the bulk of the turret and carriage would be too clumsy for the particular feed. Examples of these diverse requirements may now be noticed.

The nose of an adapter bracket either has set-screws to bind the bar or tool shank, or in preference a contractile action is gained, with a split, Fig. 6, A, or for greater strength a closed eye fitted with binder bolt and bush, B. If interchanging is necessary during the cycle of operations on each piece, a clamp handle C, suits requirements, including a key to prevent slip. Relative adjustments for amount of projection of the

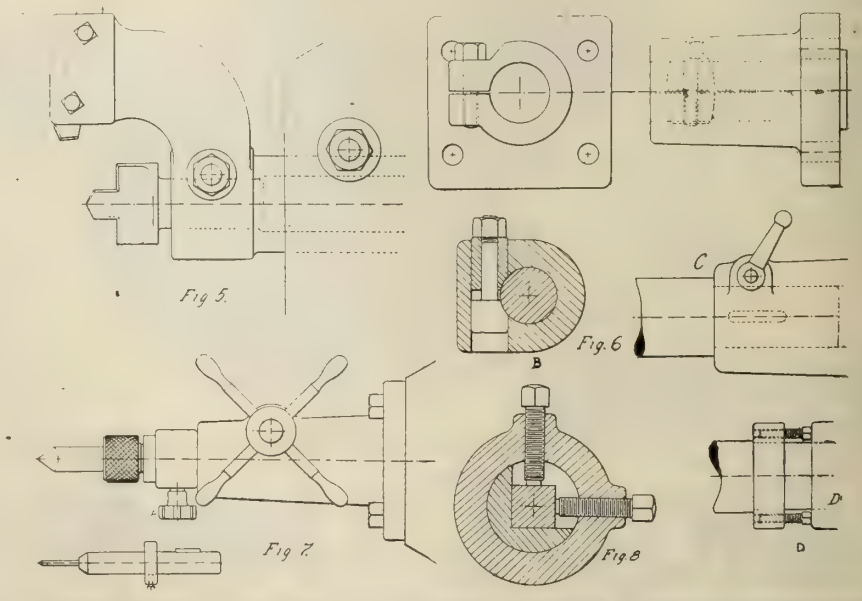

Fig. 5.—Double function adapter. Fig. 6.—A, split adapter, B, bolt and bush; C, arrangement for interchanging tools; D, adjustment collar. Fig. 7.— Adapter fitted with sensitive feed for small tools. Fig. 8.—Holding square section in round holes.

two or more tools that are interchanged can be provided for by grinding the shoulders of the bars suitably, to bed against the adapter nose; but if subsequent fine corrections are needful, a split threaded collar can be put on the bar. The trouble of cutting a screw upon the bar may, however, be avoided by fitting a plain ring as drawn at D, tapped for a pair of set-screws which thrust against the adapter face.

The delicate feed mentioned previously often happens to be required when small holes and recesses must be put into otherwise large objects involving the use of a heavy turret lathe. The adapter is then fitted with a rack-feed device to give a sensitive means of propelling the little tools, as the turret remains stationary. Fig. 7 illustrates a specimen of this character, fitted by Messrs. Alfred Herbert, Ltd., of Coventry (England) to one of their large turret lathes. A set of tools comprising centering tools, drills, etc., is used successively in the sub-adapter that is clamped in the adapter bush with the screw A, and fed with the cross-handle seen. One of the tools with its keyed shank and stop-collar may be observed in the drawing.

Floating holders exist in a variety of designs, there being usually a spring plunger beneath the bar to keep it from sagging too much, and bell-mouthing the hole. Or two plungers are located angularly underneath to afford a better balance. Alternative to this, where a long and heavy boring or reaming bar happens to project from the adapter, is the practice of bolting a sort of spoon-shaped casting to come under the bar and limit its sag.

The question of provision for holding square-shank turning or boring tools in the larger adapters depends on the frequency with which such tools may be wanted. If their use is common, the adapters may have suitable apertures slotted out to hold one or more shanks, making up necessary open spaces with distance pieces. Should only occasional gripping be desired, the neatest way lies in the adoption of filling-pieces or adapters laid in the bore, Fig. 8. Part of the circle thus becomes occupied, and the remainder of the space holds the shank. By having a curve or two inclines meeting, the shank can be rocked by suitable adjustment of the holding screws.

Space does not permit in this article to go into the question of the elaborate modifications of adapters that occur for tooling castings, extensions of the idea shown by Fig. 5. These outfits comprise multiple tools or cutters for dealing with several shoulders or faces, also slides to impart a cross-feed while the turret remains still. Somewhat unusual features also occur in certain cases, such as sloped or curved form strips attached to the adapter, to control a roller bar on the cross-slide post.

Box-tools have not, until recently, been subjects for the employment of extension adapters, as their construction generally includes a correct means of attachment to the turret. Lately, however, some of the heavy designs for turning long bars have been built simply as massive flanged castings, comparatively shallow from front to back, and their fixation to the turret face is effected by a strong box-shaped casting of suitable degree of projection, with the lower web cut through for the escape of chips and coolant. Thus a standard type of box-turner adapts itself for any lengths of turning required and the opposite flat of the turret can be used for the attachment of any other class of tool, without having to worry as to a clear hole for the passage of the bar across from the box-tool.

BETTER FACTORY FLOORS

The factory floor is an important feature, and is now being given more serious consideration by builders and owners of manufacturing plants. If the floor is not right, serious trouble is likely to ensue. It may vibrate or slump, either of which faults causes trouble with the machinery and shafting. Floors must also be made so that they are easy on the feet of workers who are obliged to stand on them for hours at a time.

One new factory has floors four inches thick, writes D. M. McAdams in a recent issue of Factory. The planks are three inches deep. A top floor of maple adds another inch. Trucks will roll smoothly over this floor, and it is easy to keep the maple boards clean and nice looking. Strength, however, is the chief reason for this heavy construction. This floor will not vibrate perceptibly when the machinery is running.

A factory with lightly built floors is likely to get out of shape and depreciate in value very quickly. One manufacturer took space in such a mushroom building not long ago. After going in he found that the shafting was bent out of true the entire length of the building. Slumping floors caused the trouble. There was a waste of power in running the shafting, and the manufacturer had to have the floors packed up and the shafting straightened before he could go on using the factory.

"Water leaked through the floors and damaged the stock on the floor below." That is not an uncommon report from large manufacturing plants. Whenever there is a fire, or even when a sprinkler head gets loose or water is spilled on the floor, it leaks through the cracks. Usually it does a lot of damage. Now, it is quite possible to prevent such accidents. Floors can be made waterproof as well as rigid. This is done by using a mixture of cement and asphalt, or mastic, as waterproof flooring is sometimes called.

In a recently finished factory building some of the floors are covered with mastic and others with waterproof paper. No water can get through. The caretakers can turn the hose on them and give them thorough washdowns as often as required. Concrete floors are hard on the feet of men and women who stand on them at work all day

THE KINEMATOGRAPH IN ENGINE DESIGN

A new type of petrol engine recently produced in Great Britain possesses many interesting features. It is designed to retain the essential advantages o the two stroke engine while avoiding certain disadvantages · · lifficulties usually met with in that type. In order to perfect the design the inventor carried out a series of experiments with the aid of a kinematograph apparatus for the study of the movement and velocity of gas. When under test this engine developed 10 horse power at 3,800 revolutions per minute, and when fitted to a motor cycle frame gave an average petrol consumption of over 60 miles per gallon. The use of castings requiring special care in the foundry has been avoided, and the machinery and erection have been made as simple as possible.

SAFETY DEVICE FOR ELECTRIC HEATERS

One of the drawbacks of electrical appliances for heating water and other liquids is that if by chance the current is switched on while the utensil, such as a kettle or urn, is empty, the element gets overheated and is apt to burn out. In order to get over this difficulty some makers introduced a safety device in the form of a metal plug which melts at a comparatively low temperature and breaks the circuit, thus preventing overheating of the element. This method works fairly well but it has the objection that in order to bring the utensil into action again a new plug must be inserted. A British firm has therefore devised a safety appliance which is equally effective in action but which does not involve any part requiring replacement. It consists of a simple mechanical arrangement which cuts off the current when the utensil boils dry. All that is necessary to restore connection is to fill the utensil with water, when the device automatically re-sets itself.

WORLD'S LARGEST LIFEBOAT

Arrangements have been made in Great Britain for building a new type of motor lifeboat which will be the largest of any yet known. Its length will be 60 ft. and its beam 15 ft. and its normal draught 4 ft. 6 in. It will be a 60 ton vessel propelled by twin screws, driven by two 75 horse-power oil engines, at a speed from 9 to 10 knots. It will be able to cruise for 100 miles without replenishing supplies. Two passenger cabins are provided, one at the bow and one at the stern, giving a total passenger carrying capacity of 150 people. Appliances are provided for supplying warmth and hot food and for rendering first aid to the injured. An interesting feature of the equipment is the provision of a searchlight and life saving net in addition to a gun for throwing a line over a vessel in distress. This vessel will be stationed on the Mersey.

Proper Care of Small Tools Increases Their Life

Workmen's Attitude Affected by Shop Conditions—Tool Room Facilities Should Prevail in Shop to Lesser Degree—Individuality Ability Basis of Plant Efficiency

By J. H. RODGERS

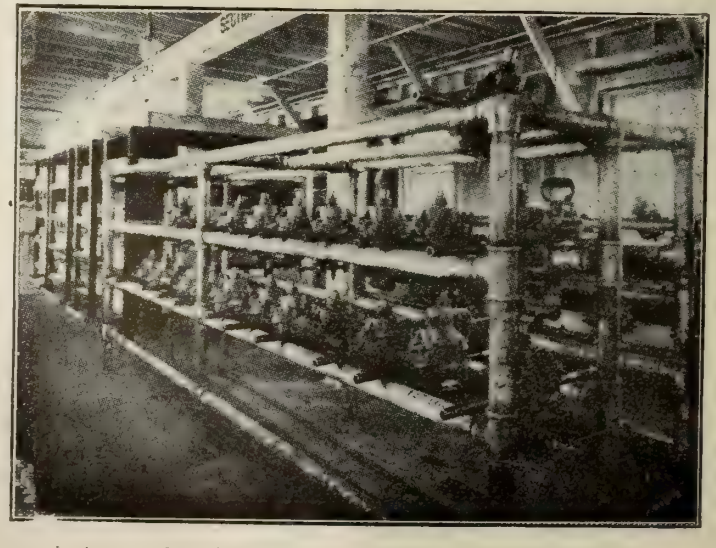
PROPER handling and storing of small tools and machine shop accessories are two essential factors in the problem of plant management. Few men fully recognize the important place that they occupy in the scheme of economic shop practice. The volume of production may not be directly affected by the amount of attention given to this matter but the ultimate efficiency of any factory is more or less affected by the policy of the shop regarding the foreman's and the employees' attitude towards the care of tools and fixtures while under their direct care or supervision.

In many manufacturing plants tool stores are provided for the purpose of keeping track of small equipment and passing out to employees when the same is required to perform the different duties for which the tools are designed. Under these conditions the tools, invariably, are given the attention necessary to maintain them in good working order for, once a tool is placed on the rack or shelf, it is not disturbed again until it is handed out for further work in the factory. These tool cribs are designed for orderly arrangement of all classes of equipment, so that the minimum amount of time is spent in obtaining the tool and handing out same to the different workmen. Likewise, when the tool is returned to the wicket it is immediately placed in its allotted place until again wanted.

But what takes place while the tool is out of the hands of the tool-room attendants? Here it might be said that "the tool is known by the company it keeps." If it so happens that the work is being performed by a careful and thoughtful mechanic the tool will be returned in as good condition as when it was taken from the crib; perhaps in better condition, as, very often, a reliable man will take sufficient interest to make any slight repair or adjustment necessary to place the tool in its proper working order.

However, should the tool be taken out by one whose only object is the completion of the work in hand, the "means to the end" may only be considered as a necessary evil, and when not in actual use may be placed in a position on the machine or the floor where it may receive more or less injury, and thereby make it less fit to properly perform its specific duties. The careless handling of costly equipment, such as gauges, cutters, precision tools, electric and pneumatic portable hand drills, etc., should not be encouraged in the shop, and workmen must school themselves to the need of thoughtful manipulation and personal supervision of such appliances when in their hands. They should realize that maintenance of efficient tool-room service is largely a question of overhead expenses, not directly related to actual production costs, and that carelessness on their part in the handling of tools needed to perform their particular work may result in replacement or repairs of parts to shop equipment, and the expense necessarily entailed must be added to overhead account and this will indirectly affect the net receipts and likewise the amount of cash available for labor cost. Individual ability is the basis of plant efficiency. As a factory personnel is made up of individuals the shop standard cannot excel the collective average.

Care of Private Tools



The majority of mechanics to-day have a varied range and supply of small tools for their own private needs and usually have a good tool box in which they are kept when not in actual service. Many men use these boxes constantly and seldom if ever place a fine precision tool on the machine or bench but use the open drawer of the box for this purpose. These men appreciate the value of the tools and the expenses incurred in acquiring the collection, and it is more than probable that shop tools (those taken from the tool-room for specific purpose) will receive the same care and attention from such men as their own private tools do.

Abuse of Shop Tools

The greatest possibility of tools becoming damaged is when they are being used by thoughtless men or when carelessness is an outstanding feature of a man or group of men. The human factor is the one that makes it almost impossible to accurately solve, in advance, the problem of shop supervision, or production.

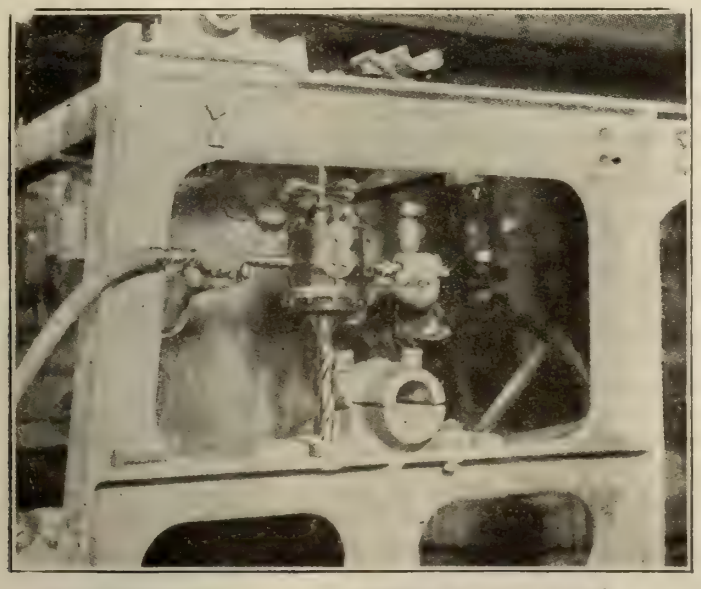
Environment is one of the things that make or mar the shop. If the men are working in an atmosphere of cheerfulness and orderliness, the spirit will dominate their entire attitude. On the other hand if discord and disorder pervade the shop, the natural consequence is that nearly every action of the average workman will reflect the general surroundings. This is particularly true in contract shops, where quantity must step aside for variety, and where one will generally see a wide range of material of every description.

Manufacturing, to-day, is done on an interchangeable basis, and the use of templates, jigs and gauges is an imperative need where volume and accuracy are the essential features. Generally speaking; tools of this character are costly to make, and not constructed to stand any abuse, so that extreme care should always be exercised when used in connection with machining or assembling of the work. In the case of jigs or fixtures, these are usually in constant use when out of the tool room, and therefore, constantly under the eye of the man doing the work. However, should it be necessary for the workman to place a certain jig or fixture to one side temporarily, some definite place should be provided, such as a nearby shelf or cupboard. The usual course is to locate it on the bench or floor. It is comparatively safe on a bench, but often becomes a target if located on the floor.

A strong and serviceable rack for pneumatic and electric tools.

The writer has in mind a certain drill jig that was being used by a workman, but owing to a rush job coming along the jig was removed from the table and placed on the floor alongside of the machine. Through some misjudgment the piece being hurried through succeeded in getting away from the operator and in its flight to the floor struck the jig, with the result that a part was broken off that required two days to repair. In every case, where it is found necessary to change fixtures, it is always advisable to forestall the possibility of accident by making sure that the other tools are out of harm's way.

Great care should be taken when using fine measuring tools around machines. If possible it is well to have a wooden shelf conveniently located so that the gauges and other instruments may be placed thereon. This is advisable for obvious reasons. These tools are often very sensitive and easily affected by change of temperature. Invariably, wood will retain the general temperature of the shop, and when precision tools are kept in contact with wood, the possibility of change is very slight. On the other hand if a gauge is used on a piece of metal that has just been machined the small volume of metal contained in the gauge will rapidly absorb the heat, and when again placed on the comparatively cold machine will cause slight but certain contraction, which, in time will affect the accuracy of the tool.



We have in mind an instance where a lathe hand was turning some 3 in. short steel shafts and was using a snap gauge for sizing. Being close to an outside wall he was using it to hang his gauge on when not in use. The following day several of the shafts were found to be slightly below size, but the operator insisted that they had been made to gauge. When the gauge was obtained from the tool-room it was found that the shafts were small. After thinking the matter over it was believed that the size of the gauge had been affected by contact with the cold wall—it being in the winter time. A few weeks later some similar shafts were going through, but in the meantime a small wooden board had been erected, several inches from the wall, and no errors were recorded. The contraction of the gauge had been sufficient to under-gauge the shaft.

Portable Tools

Portable tools, such as electric and pneumatic drills, are frequently subjected to abuse owing to the fact that they are not always given the attention they deserve. Owing to their peculiar construction and the awkward position they are often used in, they are difficult to handle and sometimes they are allowed to fall, and not too gently, to the floor, and injury often results. Under no circumstances should such tools be allowed to lay about on the floor, as damage is frequently caused by parts falling on them.

In using flexible shaft grinders care should be taken to keep the shafts as straight as possible. The fact that the shaft is flexible is no reason that the same should be used in the position of a hoop. The location of the power source may seriously affect the life of such tools. The writer has in mind a shop where one of these belt-driven flexible shaft grinders had been installed for grinding the shear on large dies. The work table had been placed in the centre of an open space but the location of the counter shaft made it necessary to use the grinder with the shaft always in the shape of a large U, and no adequate means of lubrication could be found to keep the shaft cool. It was finally decided to change the location of the drive, and this eliminated much of the trouble.

Every means should be provided to assist the workmen in keeping tools in good condition. A careful study of the needs of the shop regarding the proper facilities for temporary and permanent storing of tools, and the meeting of such requirements will more than repay the outlay necessary.

Care should be taken in removing portable tools from awkward positions.

COMBUSTION OF FUEL MOST IMPORTANT

Under ordinary conditions the ignition temperature of a fuel is less important than the maintenance of combustion. No matter how large the mass of fuel may be, whether it is a blast furnace, under a boiler, or in an ordinary household furnace, the origin of the heat necessary to raise this fuel to the ignition temperature is in the kindling which starts the fire. Hence the starting of an ordinary fire is a process depending upon the application of an outside source of heat, always at a high temperature, to some portion of the mass of coal until a part of the coal itself burns and propagates heat to the remainder. It is, however, in connection with the storing of coal in piles that the ignition temperature takes on a real significance. Coal is actually burning at all times and even at low temperatures. If the heat thus produced is sufficiently confined and air is supplied to the coal at the proper rate the temperature of the interior of the mass will rise. As the temperature rises the rate of combustion also rises and after a certain safe temperature rises the rate of combustion also rises and after a certain safe temperature is passed the process goes on quite rapidly until burning or flame results. Bulletin No. 128 of the Engineering Experiment Station of the University of Illinois, "The Ignition Temperature of Coal" by R. W. Arms makes a study of this problem with the object of determining the influence of the temperature of ignition of the various coals upon the liability to fire while in storage. In this bulletin is given a discussion of what point may actually be designated as the ignition temperature and what factors influence that point, the methods for determining the ignition temperature of different coals, and the results of tests upon the various coals used in this investigation. Copies of Bulletin No. 128 may be had without charge by addressing the Engineering Experiment Station, Urbana, Illinois.

BRITISH ELECTRICAL RESEARCH

Practically every loading section of industry in Great Britain has its organised co-operative research Association. In the case of brass, copper, and other metals not containing iron a great deal of very interesting research is now being carried on. The casting of brass, influence of impurities on the working of copper, the electric melting of non-ferrous metals, and the grinding, jointing, and polishing of such metals are being closely studied. Perhaps the most important part of this research lies in the investigation of corrosion. The production of rustless iron and steel has stimulated the brass and other industries to give attention to the causes of corrosion. It is stated that the examination of tarnishing, which is the first stage towards corrosion, has already yielded very interesting results.

The Industrial Diamond and Its Various Uses

Location of Different Fields—Sorting and Grading for Practical Application—Appraising Value and Quality—Experience Necessary for Accurate Selection—Different Settings

By W. FURNISS CLARKE, M.E.

THE SUBJECT of diamonds is a very interesting and fascinating one for the student. Volumes can be written on their history, their baleful or happy influence upon humans, and the part they have played in shaping the course of many notable lives and events.

Take as one instance, the history of the popularly known "Koh-I-Noor" (mountain of light) originally weighing 793 carats and which the Hindoo accounts deduce from the time of the God Krishna. It appears in the treasury at Delhi, and taken in conquest by Ala-ed-Din, came into the possession of the Sultan Baber of the Mogul dynasty in the year 1526.

By adventure and duplicity, the stone came into the possession of Nadir Shah, conqueror of India, from whom it was handed down through the family, to Achmed Shah, whose son Shah Sujah was eventually forced to hand it over to Runjit Singh.

British troops, at the time of the Sikh mutiny, captured Lahore, and this famous stone fell into their hands, and was presented to the late Queen Victoria in June, 1850.

When the Koh-I-Noor was shown at the exhibition in 1851, its weight was then 186 carats. Previous to its capture, it had been shamefully and unskilfully cut by Hortensio Borgio for Emperor Aurenzebe, who did not pay for the work, but instead, confiscated the whole of Borgio's possessions, and threatened him with death. A skilful workman named Voorsanger of the firm of Mr. Coster, Amsterdam, recut the stone in England, and after 456 hours of labor, transformed the lustreless crystal into a brilliant gem weighing 106-1/16 carats. The Koh-I-Noor is famed for its fire and purity, and is to day, a gem amongst the Crown Jewels of Britain.

We might proceed with these histories from the "Great Mogul" traditional Indian diamond, of 280 carats, to the "Mattam," 367 carats, which was the cause of an exceptionally cruel and bloody war, the "Braganza," 1,680 carats, the "Shah," 86 carats, the "Regent" 136¾ carats, which Napoleon wore in his sword, the "Florentine," 139½ carats, down to the later African find known as the "Cullinan" diamond weighing 3,254 carats, and which, because of its formation, was eventually cut up into 200 stones of unparalleled beauty and quality. The largest of these stones, now known as the "Stars of Africa" weighing 516½ and 309-3/16 carats repose in the British Royal Sceptre, and the Imperial State Crown respectively.

Author is Canadian manager of Furniss Clarke & Co., Montreal.

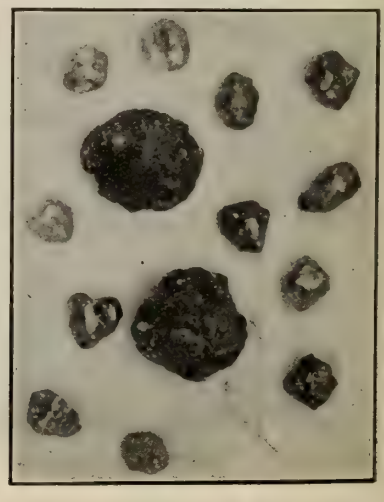
Many more noted diamonds could be mentioned if space and time would permit, each with its own peculiar or bloody history the various details of which are described in many works for that purpose. The oldest diamond mines are in India, where large quantities and some very wonderful stones were found. The Indian mines, however, are now practically abandoned, and Madras is not now the centre as it was years ago.

Diamonds were found in Brazil in 1728, and several great fields were opened. It is from Brazil that we get the black diamond, or carbon. The Brazilian fields are still large producers. Diamonds were also found in Chili, Australia, Borneo and North America, but to a limited extent. They were found in South Africa by O'Reilly in 1867, and later by Prof. Emil Cohen in 1872, since which time the mines have extended over hundreds of square miles of territory in Cape Colony and the old Vaal River State, now the Union of South Africa, and the mines are the world's largest producers at the present day.

Diamonds as a whole when mined, consist of stones of all shapes, sizes and colors. They are minutely sorted, and those suitable for gems are taken out, and after being cut and polished by expert workmen, they appear in the market in the form popularly known as "Diamonds." The balance of the sorting which has been rejected for gem purposes either because of unsuitable grain, color or other defect, are called Bort, sometimes Bortz, and it is this class of diamond we are more particularly concerned with in this article.

The Industrial Diamond

This Bort, or industrial diamond is in turn again closely sorted and graded according to its particular mine, color, shape, grain, hardness and general condition of solidity. In these grades they are put on the market for industrial purposes, all in their various sizes, and with regard to their suitability for particular work. The last grade, consisting of stones badly cracked up, small pieces, etc., are called Crushing Bort. This is crushed up in pestle and mortar to various grades of powder, and is used for cutting and polishing gems, or the various shaped diamond tools.



During all the above sorting and classifying, a tremendous amount of experience and knowledge is being used; knowledge gained only by years of continual activity in handling stones, together with close attention to every detail, variation or phenomenon. It follows that consumer should be quite sure he is dealing with a reliable importer when he is buying his diamonds or tools. As can be seen from the above descriptions, diamonds vary infinitely, and it cannot be expected of anyone who has not made a life study of them, to be able to accurately judge from a parcel of stones, their exact values and their suitability under given circumstances. It is therefore advisable to deal only with those who have the knowledge, and in whom every confidence can be placed, to supply proper and suitable diamonds for the work, at fair prices.

Except in extreme cases of business expediency, when dealing with an experienced firm, the price is a sure indication of the value offered, be it high or low, for there is a standard starting price on all industrial stones. This may not hold good when dealing with the casual dealer who has not the experience necessary to appraise and determine the actual value or condition of such a variable commodity.

Practical Utilization

We now turn our attention to the actual use of diamonds for industrial purposes, and a few hints from practical experience will be in order. There is no question but that the diamond is very much harder than any of the materials it could be called upon to cut, and although diamonds themselves vary in hardness, this variation is negligible in comparison with the great difference in hardness between the softest diamond and say, carbide of silicon or corundum. At the same time, the existing difference in the hardness of various classes of diamonds is a point which must be taken care of, and it is in this regard that the experience of a practical diamond man is valuable, so that the most economical sort of stone will be used for the work in hand.

Grinding wheel dressers.—The diam-

Industrial diamonds in the rough.

grain of the grinding wheel, and the following table will give some idea of the size of diamond required in most cases:

Dia. of Wheel inches	Size of Diamond Carats
6 and under	½
8	¾
12	1
16	1¼
20	1½
24	2
30	2½
36	3
42	3½ to 4

As regards the thickness and grain of the wheel, this is covered by the quality of the diamond chosen, its shape and general condition. Too large a diamond is not necessary, but it must be large enough to allow of secure setting. Nor is it imperative to choose a perfect stone in all cases, when an ordinary stone will do, for the more perfect the stone, the higher the price must be. It is a good plan to acquaint your dealer with the class of work you are handling, and the size and grain of the wheels you use, leaving it to him to make you a tool complete, trying one or two tools of various prices, and with the shop records, determine the most efficient tool for your purposes in connection with price. All reliable tool makers keep records of the diamonds they supply, and can within limits, keep your tools to that standard, with probably slight variation in price as affected by the diamond market.

Suitable Mounting

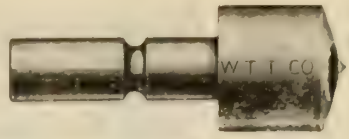
The diamond should be mounted in an approved setting, with cuttting edge exposed. Great care must be taken, and if an experienced man is not on hand, it is far better to have the work done by those who employ experts for this work. Many a good diamond is ruined because of incorrect setting.

The "cast" mount is the best, because it grips the diamond properly, but the metal used, must have a low melting temperature. Molten steel is sometimes used, but this is too severe, and is extremely liable to injure the temper of the stone, and make it brittle. This injury is exaggerated each time the stone is re-set, and consequently its service is shortened considerably. This difficulty has been overcome, and special alloys of sufficient hardness, and with low fusion points are used by the more particular and progressive diamond tool makers.

The copper setting is used successfully for very small stones, but is dangerous for larger sizes, and not uniformly good. The diamond holder must be of a size and shape to suit the grinding machine equipment, and it must be held firmly and without chatter in such a position, that the diamond will be fairly well on the centre of wheel, and working in a straight line across its face. A round holder is better than a square one.

Take very light cuts, and keep the diamond cool by allowing a plentiful stream of water. Only the diamond must be in contact with the wheel, and not the holder, otherwise the metal will be ground away and weaken the setting, which is dangerous. Heavy cuts should not be taken, for there is a risk of breaking the diamond not only by making it take too heavy a load, but by overheating it and causing unequal expansion with its setting. The finest diamond can easily be cracked or crushed by sudden shock, a sharp blow, or excessive pressure.

Method of Using



When using a diamond set in a hand tool, the tool must be firmly held against some part of the machine. It is nearly impossible to dress a wheel absolutely true with a hand tool, and it is necessary therefore, to use a fixed dresser in order to obtain a perfect cutting wheel and accurate work. Use the hand dresser only on very ordinary work. When the cutting edge is worn, the diamond should be re-set, so that a new cutting edge can be exposed. This will prolong the service, for after the cutting edges have gone past a certain point, the diamond wears away very rapidly. Another point to consider is, that a blunt diamond will overheat very quickly, it will also burnish the face of the wheel and cause glazing. This means the use of more power in return for indifferent work, and a drop in production. A lot of trouble has been caused in this way, and all sorts of others things have been blamed for it. A blunt diamond is almost useless.

In the case of re-setting, care must be used in taking the diamond out of its setting, and here again, unless there is a man on hand who understands the work thoroughly, it is safer and cheaper to send the tool to a maker, who is equipped to do the work correctly and without accident. If the above suggestions are followed, the maximum value can be obtained from each diamond, and expense kept down to the lowest possible point.

Diamond turning tools are rapidly coming into favor, although "first cost" has acted prejudicially against them. This is quite natural, but enquiry and experience will show that it is a mistaken idea. There are many operations being performed with difficulty and expense, and steel tools, which could be more accurately done by the proper diamond tool, with an infinite saving of labor and time. A Bortz diamond can be cut along with its cleavage planes and a very sharp edge is obtained which can be shaped into either a square or round nosed tool.

Diamond pointed turning tool.

Diamond pointed tool holder.

Sustained Accuracy

Black diamonds, or carbons, lend themselves readily for use in special tools, because they are of non-crystalline form. They will not give as keen a cutting edge as the Bortz will, but they are tougher and will not chip as easily. A diamond tool when once "set-up" in the machine will continue to size its work very accurately for long periods (in cases, of months duration) and this, upon hard and gritty materials which will, in a matter of minutes wear the keen edge from the finest high speed steel tool. This of course, effects a great saving of time resharpening the tool and setting it up in the machine again. In short, they effect a vast economy when properly handled in such materials as fibre, hard rubber, ivory, brass, bronze, copper, aluminum, celluloid, mica, paper, and cotton rolls, etc.

The writer's firm have gone so far as to make tools for taking light cuts in Stellite and various other operations in steel quite successfully, and with reduced costs. When the natural fear of using such a thing as a diamond is overcome, together with the sceptical attitude as regards costs, the diamond tool will take its well deserved place amongst standard equipment.

The same care must be taken with this class of tool as is taken with the diamond dresser, both as regards taking light cuts, and having the tool firmly and properly secured in the machine. After the tool has been at work until the cutting edge becomes dull, it simply is a matter of returning it to the maker to be re-sharpened or re-ground, and the cost is trifling when it is considered how much work the repaired tool will perform. A properly made diamond tool can be sharpened many times, and the original tool will last many months, probably a year or two, according to the kind of work it is given to do.

Various Applications

There are many other tools made with diamond points, such as optical drills, cutters, glaziers' tools, engine turning tools, chasers, etc. There is also the diamond wire drawing die which consists of a diamond set in a casing, and which has a shaped hole drilled through its centre of the size of wire required. These tools are of course, specialties, and instruction is generally obtainable from the makers suitable to their own special designs.

Another branch of diamond tools is the stone saw tooth. Circular saws as large as 98 inches in diameter are fitted with these tools. They saw through blocks of stone 3ft. 6in. thick with ease, leav-

(Continued on Page 27)

Great Accuracy Developed in Gear Tooth Form

Inserted Tooth Almost Obsolete—Gears With Cast Teeth Used Only for Heavy Rough Work—Small Gears Often Made by Die Casting Process—Cut Gears Most Efficient

By CHESTER B. HAMILTON, Jr., B.A.Sc., M.E.

IN THIS aticle the author continues to deal with the classification of gears and their respective applications. The next type to be given consideration will be the mortice gear. This class of gear is almost obsolete, though some are still used. It must be considered, however, for two reasons; first, as a link with the past and, second, as one of the first successful attempts to make heavy power gears that would be reasonably silent at high speed and correspondingly free from vibration and its attendant ill effects.

The mortice gear, with its inserted wooden teeth, held in place by driven keys, is a lineal descendant of the pin cog wheel and lantern pinion of medieval times. The teeth of the mortice wheel are usually of some such material as hard maple boiled in oil, the wheel itself being cast iron with cored mortices. The tooth thickness is about sixty five per cent. of the circular pitch. The pinion which mates with the mortice wheel would usually be cast iron with cast teeth, dressed by chipping and filing to a better finish than required where two cast iron gears mate. The thickness at the pitch line of the iron tooth would be thirty-five per cent of the pitch. The form of the tooth curve was nearly always epicycloidal, for at the time the use of mortice wheels was at its height the involute tooth curve had not been developed. Both spur and bevel gears were common. The type does not appear to have been adaptable to helical, and not very much to worm-gears.

Machine Made Teeth

The teeth, formerly made by hand, were later made in various ingenious fixtures applied to the narrow-bladed or pattern makers' hand saw, or they were finished on a revolving sand paper roll with the aid of a pair of tooth-form templet, one attached temporarily to each end of the work and taking bearing against a smooth portion of the roll beyond the sand paper. The latter method was particularly favored for making a nice job on the teeth of bevel gears, as one templet could be made much larger than the other, and their size and distance apart calculated to give the correct taper to the teeth. Later on, William Gleason adapted the gear planer to finish inserted wood teeth in place in the gear, with precision as to form and pitch, as well as angle in the case of bevels, by mounting a small circular saw in place of the planer tool on the reciprocating head of the machine. The saw revolves in a horizontal plane and its farthest out point describes the tooth, under control of a templet. These gears when run with an iron mate with cut teeth, planed on a similar machine, give really excellent service.

At the present day almost the only mortice gears to be found are the bevels in small water turbine installations, which transmit the power from the vertical turbine shaft to the horizontal main line shaft into the mill. For this work, they appear to be fairly satisfactory.

Gears With Cast Teeth

For many years the great majority of gears were made with cast teeth, and for some purposes this class of gear is still used. It is due, however, to the deficiencies of the cast tooth that the gears lagged many years behind other mechanical work in relative progress. Only since accurate cut teeth have been available has the machine designer been able to use the gears freely in his constructions without feeling that they were the weak link in the system. This applies not only to the actual servicibility of this part of the apparatus, but also its saleability. Many a machine has been judged according to the number of gears it contained.

Cast gears are still used with some success on very heavy slow moving work with large coarse teeth. There are two reasons for this. One is economic. These heavy slow-moving jobs are usually for intermittent use and like any other article that is only used occasionally, the tendency is to hold the first cost as low as possible, in order to keep the operating overhead per unit of use as low as possible. The other reason is mechanical. The time element from tooth to tooth is at a maximum with coarse pitches and with slow revolution, and the apparatus has time to adjust itself to inequalities of angular velocity which, in faster running machinery would combine with the inertia to produce enormous stresses.

Die Cast Gears

The name cast tooth gear would appear to cover all gears in which the teeth are formed in a fluid state by being run into a mould and allowed to solidify. The name as commonly used however, does not cover the special class known as die cast gears. In this the fluid metal is forced under pressure, considerably greater than ordinarily supplied by gravity, into an accurately machined die or mould, which it thus fills to the last minute corner. Pressure is maintained during solidification. The metal is usually an alloy of relatively low melting point which can be cast with a negligible scale. As the casting may be forced out of the die mechanically when solid, the draft required is also negligible in most cases. Die casting can be made to produce a very high-class job, strength and durability of metal being the only disadvantages.

In general, cast gears are made in sand moulds from either gray iron or steel. Malleable iron is not a suitable material for gears either cut or cast. It is the reverse of a high class case-hardened, heat-treated gear, for it is soft on the surface where it should be hard, and rigid in the core where it should be tough. Air furnace iron is not much used, as any one wishing for refinements would naturally either use steel or have the gears cut. The great majority of cast gears are made of cupola gray iron of a rather strong mixture of low shrinkage co-efficient, low sulphur and phosphorus. For cut gears the shrinkage is not such a vital matter, and the silicon must be kept up for the sake of machinability. Semi-steel is used to a considerable extent, either made by charging steel scrap in the cupola, or adding turnings in the bull ladle. The latter is a doubtful expedient with cast tooth gears, as it may reduce the fluidity so much as to prevent a good filling of every corner of every tooth, and a gear like a chain is no better than its weakest member. Outside of the agricultural implement and such trades, steel is really the only first class material for cast gears. For small gears the converter steel has some advantages over open hearth on account of its fluidity. From the point of view of cleanness the case is reversed. The electric furnace by its fine temperature control permits the heat to be as high as needed for the class of work and no higher. It also has the advantage of a deader melt with less boiling than either of the others, and consequently tends to produce the soundest castings.

Cast Gear Molds

The moulds in which gears are cast may be either dry sand or green sand, though the latter is by far the most common. Shrouded pinions are frequently cast with the teeth in a dry sand ring which is set in the middle of the two-part box, while the top and bottom shrouds and hubs, if any, are in green sand in the cope and drag respectively. This saves the use of a three-part box, which is always a nuisance. Worm wheels, on account of their concave face may be treated similarly. Segmental cores for large work are not a success,

---

Author is President of the Hamilton Gear and Machine Co., and a member of the American Society Mechanical Engineers; Engineering Institute of Canada; Society of Automotive Engineers; American Gear Manufacturers' Association, Steel Treating Research Society; Standardization Committee of A.G.M.A.; Associate Member of American Institute of Electrical Engineers.

for it is practically impossible to hold to pitch at the points, and the resulting gear has an assortment of thick or thin teeth at regular intervals. A segment pattern is the better way if the expense of a full pattern must be avoided, and a really skilful moulder can produce a creditable job with a surprisingly short segment by sweeping and laying off on the bottom of the mould. This refers of course to very large work only. It is worthy of note here that there is no draft on work moulded from short segments as the pattern is withdrawn radially inwards, and the space within the rim built up afterwards, perhaps with dry sand cores.

Moulding Machine Practice

Moulding machines of practically every type can be used in the production of cast gears. A favorite for small and medium-sized work is the stripper plate machine, because it eliminates draft. In the Pittsburgh district there is in use a special type of moulding machine for very heavy work such as roll pinions. In appearance these machines, which are made in various sizes, resemble boring mills but of much lighter construction. The table may be revolved for sweeping, or indexed tooth by tooth as the job progresses. What corresponds to the boring bar, carries the pattern segment which generally consists of only two teeth, and may be only one. By traversing the pattern holder toward the center the pattern is withdrawn in a radial direction, which permits shrouded pinions or double helical gears to be moulded. The moulding of bevel gears is of course a comparatively simple matter, provided the tooth flanks are not under cut, as the whole job is essentially conical. The under cutting is prevented by laying out the pattern with a high pressure angle. This point can be considered better further on in connection with cut gears.

The shortcomings of cast tooth gears are fairly obvious, but it may be well to state them. They are noisy, because the surface is rough and the pitch usually far from uniform. The noise is only a demonstration of vibrations which tend to wreck the whole machine. They absorb power because of the friction of the rough surfaces and the varying angular velocity of the mass. They are weaker than the corresponding cut gear because the load is concentrated on the high spots of the rough and often badly shaped tooth face. These high spots are quite as likely to be at a corner as anywhere else, giving maximum stress. When worn to a reasonably smooth surface they suffer from excessive back lash.

Cut Gears

This subject will be more fully developed in another section, and will here be touched only briefly. It had long been customary to dress the teeth of cast metal gears with chisel and file. The desire to eliminate the cost of this tedious and unsatisfactory operation, as well as the call for better gears for higher speeds, led to the development of cut gears. It was natural for the skilled workman, worrying over some particularly bad sample from the foundry, which must be dressed to templet, to speculate on means for "finishing the whole tooth at one pass of the tool," or "making a machine to use the template, instead of hand and eye." With the development of machine tools this gradually came to pass. There were three lines of development. The first was the planing method, using a tool of the full size of the space between two teeth which was fed radially into the gear while it traveled in a direction parallel to the axis. It is natural that this should have been first for, next to the lathe and drill, the planer was one of the earliest machine tools, and was consequently in wider use and better developed than other types. This method of gear cutting was not satisfactory for several reasons, and attempts to overcome these difficulties gave rise to the second and third lines of development.

Such a depth of cut and mass of metal had to be removed in coarse pitches so that the ordinary planer was a slow producer. Two methods were developed. One was to replace the planer by the milling machine, which is especially adapted to deep cuts in solid metal with formed tools. The other was to not cast the rim solid, but toothed and thicken the teeth enough for a good planer cut on the sides. Then the formed tool was replaced by a single point planer tool which was controlled by a templet device so that as it fed down the side of the tooth, its point traversed the desired tooth curve. A templet and a tool on the other hand would finish the opposite side of the tooth. This idea, developed in special machines of the slotter and shaper types, is the modern way of cutting coarse pitch gears. The milling machine method, above referred to, worked well, but two objections arose. On large gears the cost of the formed cutter was great, and a careless operator could destroy it in a few minutes, whereas with the Templet machine the tools are cheap and the Templet is beyond injury. Also, no one would think of keeping spare templets, while a stock of spare cutters is a practical necessity.

Milling Gear Teeth

As milling practice developed, however, the speed, accuracy and convenience of this method of producing gears of small and medium pitches overcame its disadvantages for all but large work. Better and cheaper cutters became available from the larger manufacturers, Brown & Sharpe in particular being pioneers, and special machines, and, later, automatics were brought out containing many refinements. Up to recent years the form milling process has been the standard method of production of spur gears. Of late the generating process has tended to supersede milling, especially where the generating tool is of a type that can be ground all over after hardening. As to bevel gears, the milling process was never theoretically correct, really no more than a makeshift, and their development was altogether along the templet shaper line, and later the generating bevel gear shaper. In the case of worm gears also the form milling process was not correct, and in this case a generating process, namely, hobbing, was used from the first.

Rolling Process

The forming of the teeth of a gear by rolling the blank with a die by some such process as is used for rolling the threads on bolts, is a very attractive process in theory, but attended by many serious practical difficulties. It is being worked to a very limited extent in the United States by the patentee of certain specialized machines which he has devised. The process is started at a forging temperature. The blank is fixed by a quick-clamping device, onto the overhanging end of a powerful arbor. The die, which has the form of a gear, is on an adjacent arbor, located a little way back from the position which it will occupy when fully in mesh with the finished gear, and removed from that position in a direction perpendicular to the teeth. The die and the hot blank, through their arbors are connected by a train of gears giving them the relative number of revolutions dictated by the number of teeth in the die and the number to be formed in the work. Thus tool and work have the same pitch line velocity. With the work at a forging heat, and die and work both revolving at high speed, the die is forced into the work and the teeth are formed by the moulding generating process as the hot and plastic metal rolls in mesh with the rigid teeth of the die. The rolling is continued till far below all critical points of the steel, and on account of this low finishing temperature the quality of the metal is particularly good.

For spur gears the shafts are parallel and the die is a spur gear or pinion with accurately generated involute tooth curves. For bevel gears the die is a flat crown gear of 90 degrees pitch angle. Any form of gear which has both shafts in the same plane could be generated by this process. That is to say, any form where the tooth action was practically pure rolling, and the sliding was negligible. Herringbone or other special tooth profile can be generated in both the spur and bevel. While this process has been under development for quite a number of years, its commercial progress has been slight; the only product on the market being one size of bevel for rear axles of a cheap motor car.

To be Continued

Any oil that contains animal fat, while a desirable lubricant for a great many metals, is a bad element on any machine. Animal fat contains more or less acid, and unless the acid is eliminated, or neutralized, it will rust and gum up the machine.

Safety Features in the Operation of Lathes

Tools Should Always be Firmly Secured—Keep Bolts, Clamps and Gibs Tight—Provide Guards for Flying Chips—Protection and Production Go Together

By H. ALTON

IN THE OPERATION of a lathe many accidents occur as a result of the displacement or breakage of the tools, or of the piece that is being machined. When a tool is insecurely or improperly set, it often works loose and causes trouble in many ways. Frequently it digs into the work, and unless the lathe is stopped immediately, the tool may be broken or forced out of the tool post. If this does not occur, the work may be torn out of the chuck or the centres, or all of these things may happen at once. In such an event the operator of the lathe is very likely to be injured, especially if the machine is a large one and the work is heavy. A "safety first" measure is to select a tool that is suited to the work in hand, make sure that it is in good condition, and be certain that the setting is right, and that it is held rigidly. In operating lathes that are more or less worn, it should be remembered that when a lathe spindle is loose in its bearings, and the carriage slack on the ways, a good deal of vibration and chatter is set up that are contributory causes to work shifting, bolts or clamps loosening, all of which are factors that frequently cause an accident.

Eye Protection

When metal such as brass is being machined, the eyes of the operator are endangered by flying chips of metal. It is a wise precaution to use goggles when working under these conditions, and foremen should see that they are worn when the occasion demands it. Guards of stout wire-mesh, framed and secured to the tool posts, so that they will intercept flying chips, have been used extensively. A guard of this kind is shown in Fig. 1. Better protection is afforded by the use of heavy plate glass as illustrated in Fig. 2. Care should be taken, however, to keep it clean, so that the work can be seen distinctly at all times. In constructing a guard of this kind, it should be made in a manner that permits of easy adjustments and removal. To prevent glass chips from flying in case the guard is broken, the glass should consist of two thicknesses, cemented together with a thin film of transparent celluloid.

Chips that lodge in the eye cause severe pain, and the injuries they inflict are often followed with serious results. Unskilled treatment of such injuries adds greatly to the danger of complications. Therefore it is the best course to consult a physician at the earliest possible moment.

Filing in the Lathe

Filing, if not done intelligently, is a hazardous operation. Every machinist knows that he is taking chances when he uses a file without a handle, yet this is done every day. The man in charge of the shop should see that such a practice is discontinued. The position in which the file is held is also of great importance, because even with the handle in place the file may be pushed back against the operator's abdomen with great violence. A file should be held in such a way that, in case it is forced back, the handle will be pushed to the side of the body instead of directly against it. Filing irregularly shaped pieces with projecting portions, must be carefully done, and the operator should keep his attention concentrated on the work. Rolling up the sleeves is important, as loose sleeves will catch on all projections from the work or from the face-plate or chuck. When it is necessary to lean over to inspect revolving work of an eccentric or unsymmetrical nature, an operator should always keep in mind that there is danger of being struck by some portion of it.

Set Screws and Other Projections

Many old lathe dogs with projecting set screws were, and still are, the source of accidents. Such designs are being replaced in a large measure by dogs in which safety or guarded set-screws are used, or by types that have no projecting parts. In as far as it is practicable, all face-plates and chucks should present smooth even surfaces with no set screws or other projections upon them. When adjusting a chuck, be sure to remove the wrench before starting the lathe.

Using Bar Stock on Hollow Spindle Machines

Pins, bolts, studs, screws and such products are often machined from long bars, which at the beginning of operations project several feet beyond the head stock of the lathe. These bars frequently revolve at a high rate of speed, and constitute a source of danger even greater than that of unguarded shafting. In small bars they will whip about considerably and if unguarded would be a very prolific source of accidents. A simple and inexpensive guard is provided by placing a tube over the revolving end of the bar and support the tube as shown in Fig. 3. If it is not possible to place a guard over the rod then the space should be railed off temporarily.

Belts and Pulleys

Careful attention must be given driving belts, pulleys and shafting used to drive lathes. A large proportion of lathes are provided with cone pulleys for speed changes, and the belts have to be frequently changed from one step of the pulley to another. Mechanical belt shifters may be utilized to advantage to minimize hazard.

Lathe operators usually grasp the belt while the power is off, to turn the work to a desired position for making certain settings or adjustments. For this reason it is advisable that endless belts with cemented joints be used, but it is very troublesome and expensive to take up slack that is bound to develop in such a drive belt. A belt that is laced with a leather lace presents the least danger to the hands of the lathe operator. Metal belt fasteners, wire clips, or wire lacings are the source of many nasty cuts and tears of the hands of the operators. The handle of the belt shifter which operates the belt from the line shaft to the countershaft, should be located in a position where it is conveniently and quickly accessible, in order that there may be no delay in stopping the machine in a case of emergency.

In many shops the individual motor drive has been applied to lathes, and in some of these instances the motors are geared directly to the machines, while in others the power is transmittted by silent chains and sprockets or by short belt drives. From a standpoint of safety this application of power is often desirable.

Adequate protection and effective guards should be provided for all gears,
